

**The package *luadraw***  
version 2.4  
2d and 3d drawing with lua (and tikz).

<https://github.com/pfradin/luadraw>

**Abstract**

The *luadraw* package defines the environment of the same name, which lets you create mathematical graphs using the Lua language. These graphs are ultimately drawn by tikz (and automatically saved), so why make them in Lua? Because Lua brings all the power of a simple, efficient programming language with good computational capabilities.

Patrick Fradin

46	Write on a cylinder . . . . .	141

## 2D Drawing

Figure 1: A first example: three sub-figures in the same graph

### I Introduction

#### 1) Prerequisites

- In the preamble, you must declare the *luadraw* package: `\usepackage[global options]{luadraw}`
- Compilation is done with LuaLatex **exclusively**.
- The colors in the *luadraw* environment are strings that must correspond to colors known to tikz. It is strongly recommended to use the *xcolor* package with the *svgnames* option.

Regardless of the global options chosen, this package loads the *luadraw\_graph2d.lua* module, which defines the *graph* class, and provides the *luadraw* environment for creating graphs in Lua.

**Global package options** : *noexec*, *3d*, and *cachedir=*.

- *noexec*: When this global option is specified, the default value of the *exec* option for the *luadraw* environment will be false (and no longer true).

- *3d*: When this global option is specified, the *luadraw\_graph3d.lua* module is also loaded. This module also defines the *graph3d* class (which relies on the *graph* class) for 3D drawings.
- *cachedir* = <folder>: By default, the created files are saved in the *\_luadraw* folder, which is a subfolder of the current folder (containing the master document). This folder can be changed with the *cachedir* option, for example *cachedir* = {tikz}.

**NB:** In this chapter, we will not discuss the *3d* option. This is the subject of the next chapter. We will therefore only discuss the 2d version.

When a graph is finished, it is exported in tikz format, so this package also loads the tikz package and the libraries:

- *patterns*
- *plotmarks*
- *arrows.meta*
- *decorations.markings*

Graphs are created in a *luadraw* environment, which calls *luacode*, so the lua language must be used in this environment:

```
\begin{luadraw}{ name=<filename>, exec=true/false, auto=true/false }
-- create a new graph with a local name
local g = graph:new{ window={x1,x2,y1,y2,xscale,yscale}, margin={top,right,bottom,left},
size={width,height,ratio}, bg="color", border=true/false }
-- build the g chart
graphic instructions in Lua language ...
-- display the g chart and save it in the <filename>.tkz file
g:Show()
-- or save it only in the <filename>.tkz file
g:Save()
\end{luadraw}
```

**Saving the .tkz file** : the chart is exported in tikz format to a file (with the *tkz* extension). By default, it is saved in the *\_luadraw* folder, which is a subfolder of the current folder (containing the master document), but it is possible to specify a path to another subfolder. with the global option *cachedir*=.

## 2) Environment Options

These are:

- *name* = ...: Allows you to name the produced tikz file. It is given a name without an extension (this will be automatically added; it is *.tkz*). If this option is omitted, then a default name is the name of the master file followed by a number.
- *exec* = *true/false*: Allows you to execute or not the Lua code included in the environment. By default, this option is true, **UNLESS** if the global option *noexec* was mentioned in the preamble with the package declaration. When a complex graph that requires a lot of calculations is ready, it may be useful to add the *exec=false* option. This will prevent recalculations of the same graph for future compilations.

*auto* = *true/false*: Allows you to automatically include or exclude the tikz file in place of the *luadraw* environment when the *exec* option is set to false. By default, the *auto* option is true.

## 3) The cpx (complex) class

It is automatically loaded by the *luadraw\_graph2d* module and therefore when the *luadraw* package is loaded. This class allows you to manipulate complex numbers and perform common calculations. We create a complex number with the function **Z(a,b)** for  $a + i \times b$ , or with the function **Zp(r,theta)** for  $r \times e^{i\theta}$  in polar coordinates.

- Example: *local z = Z(a,b)* will create the complex number corresponding to  $a + i \times b$  in the variable *z*. We then access the real and imaginary parts of *z* like this: *z.re* and *z.im*.

- **Warning:** A real number  $x$  is not considered complex by Lua. However, the functions provided for graphical constructions perform the verification and conversion from real to complex. However, we can use  $Z(x,0)$  instead of  $x$ .
- The usual operators have been overloaded, allowing the use of the usual symbols, namely:  $+$ ,  $\times$ ,  $-$ ,  $/$ , as well as the equality test with  $=$ . When a calculation fails, the returned result should normally be equal to *nil*. In addition, the following functions are added (dot notation must be used in Lua):
  - modulus: **cpx.abs(z)**,
  - modulus squared: **cpx.abs2(z)**,
  - normalization: **cpx.normalize(z)** (returns *nil* if  $z$  is null),
  - norm 1: **cpx.N1(z)**,
  - main argument: **cpx.arg(z)**,
  - conjugate: **cpx.bar(z)**,
  - complex exponential: **cpx.exp(z)**,
  - scalar product: **cpx.dot(z1,z2)**, where the complex numbers represent vector affixes,
  - determinant: **cpx.det(z1,z2)**,
  - the oriented angle (in radians) between two non-zero vectors: **cpx.angle(z1,z2)**
  - rounding: **cpx.round(z, number of decimals)**,
  - the function: **cpx.isNul(z)** tests whether the real and imaginary parts of  $z$  are in absolute value less than a variable *epsilon* which is equal to  $1e-16$  by default.

The last function returns a Boolean, the bar, exponential, and round functions return a complex number, and the others return a real number.

We also have the constant *cpx.I* which represents the pure imaginary  $i$ .

Example:

```
1 local i = cpx.I
2 local A = 2+3*i
```

The multiplication symbol is required.

#### 4) Displaying a Variable in the Terminal

The instruction **whatis(variable,msg)** displays the type of the *variable* and its contents in the terminal during compilation. Recognized types include the predefined types plus: *complex number*, *list of (complex) numbers*, and *list of lists of (complex) numbers*. The argument *msg* is an optional string (empty by default) which is displayed with the type to locate the variable in the terminal.

#### 5) Creating a Graph

As seen above, creation is done in a *luadraw* environment. This creation is done by naming the graph:

```
1 local g = graph:new{ window={x1,x2,y1,y2,xscale,yscale}, margin={left,right,top,bottom},
2 size={width,height,ratio}, bg="color", border=true/false, bbox=true/false, pictureoptions="" }
```

The *graph* class is defined in the *luadraw* package. This class is instantiated by invoking its constructor and giving it a name (here it's *g*). This is done locally so that the graph *g* thus created will no longer exist once it leaves the environment (otherwise *g* would remain in memory until the end of the document).

- The (optional) parameter *window* defines the  $\mathbf{R}^2$  block corresponding to the graph: it is  $[x_1, x_2] \times [y_1, y_2]$ . The *xscale* and *yscale* parameters are optional and set to 1 by default; they represent the scale (cm per unit) on the axes. By default, we have *window* =  $\{-5.5, -5.5, 1, 1\}$ .
- The (optional) *margin* parameter sets the margins around the graph in cm. By default, we have *margin* =  $\{0.5, 0.5, 0.5, 0.5\}$ .

- The (optional) *size* parameter allows you to impose a size (in cm, including margins) for the graph. The *ratio* argument corresponds to the desired scale ratio (*xscale/yscale*). A ratio of 1 will result in an orthonormal coordinate system, and if the ratio is not specified, the default ratio is retained. Using this parameter will modify the values of *xscale* and *yscale* to obtain the correct sizes. By default, the size is  $11 \times 11$  (in cm) with margins ( $10 \times 10$  without margins).
- The (optional) *bg* parameter allows you to define a background color for the graph. This color is a string representing a color for tikz. By default, this string is empty, meaning the background will not be painted.
- The (optional) *border* parameter indicates whether or not a frame should be drawn around the graph (including the margins). By default, this parameter is set to *false*.
- The (optional) *bbox* parameter indicates whether a bounding box should be added to the graph so that it has the desired size. Everything outside of it is clipped by tikz. By default, this parameter is set to *true*. With the value *false*, no bounding box is added, but everything outside the 2D window, except for the paths, is clipped by luadraw. The graph size can be smaller than the requested size.
- The (optional) parameter *pictureoptions* is a string containing options that will be passed to *tikzpicture* like this:

```
\begin{tikzpicture}[line join=round <,pictureoptions>]
```

### Graph construction.

- The instantiated object (*g* in the example) has several methods for drawing (segments, lines, curves, etc.). Drawing instructions are not sent directly to T<sub>E</sub>X; they are stored as strings in a table that is a property of the *g* object. The **g:Show()** method will send these instructions to T<sub>E</sub>X while saving them in a text file.<sup>1</sup> The **g:Save()** method saves the graph in the file designated by the (environment) option *name* but without sending the instructions to T<sub>E</sub>X.
- The current graph can be saved to another file with the **g:Savetofile(<filename with extension>)** method.
- A current graph can be reset, i.e., delete all elements already created, with the **g:Cleargraph()** method.
- The *luadraw* package also provides a number of mathematical functions, as well as functions for calculating lists (tables) of complex numbers, geometric transformations, etc.

### Coordinate system. Location

- The instantiated object (*g* in the example) has:
  1. An original view: this is the  $\mathbf{R}^2$  block defined by the *window* option at creation. This **must not be modified** subsequently.
  2. A current view: this is a  $\mathbf{R}^2$  block that must be included in the original view; anything outside this block will be clipped. By default, the current view is the original view. To retrieve the current view, you can use the **g:Getview()** method, which returns a table  $\{x1, x2, y1, y2\}$ , representing the block  $[x1, x2] \times [y1, y2]$ .
  3. A transformation matrix: this is initialized to the identity matrix. During a drawing instruction, the points are automatically transformed by this matrix before being sent to tikz.
  4. A coordinate system (Cartesian coordinate system) linked to the current view; this is the user's coordinate system. By default, this is the canonical coordinate system of  $\mathbf{R}^2$ , but it is possible to change it. Let's say the current view is the  $[-5, 5] \times [-5, 5]$  block. It is possible, for example, to decide that this block represents the  $[-1, 12]$  interval for the abscissas and the  $[0, 8]$  interval for the ordinates. The method that makes this change will modify the graph's transformation matrix, so that for the user, everything happens as if they were in the  $[-1, 12] \times [0, 8]$  block. The intervals of the user's coordinate system can be retrieved using the methods: **g:Xinf()**, **g:Xsup()**, **g:Yinf()**, and **g:Ysup()**.
- Complex numbers are used to represent points or vectors in the user's Cartesian coordinate system.

<sup>1</sup>This file will contain a *tikzpicture* environment.

- In the tikz export, the coordinates will be different because the lower left corner (excluding margins) will have coordinates (0,0), and the upper right corner (excluding margins) will have coordinates corresponding to the size (excluding margins) of the graph, and with 1 cm per unit on both axes. This means that normally, tikz should only handle "small" numbers.
- The conversion is done automatically with the **g:strCoord(x,y)** method, which returns a string of the form  $(a,b)$ , where  $a$  and  $b$  are the coordinates for tikz, or with the **g:Coord(z)** method, which also returns a string of the form  $(a,b)$  representing the tikz coordinates of the point with affix  $z$  in the user's coordinate system.

## 6) Can we use tikz directly in the *luadraw* environment?

Suppose we are creating a graph named  $g$  in a *luadraw* environment. It is possible to write a tikz instruction during this creation, but not using `tex.sprint("<tikz instruction>")`, because then this instruction would not be part of the graph  $g$ . To do this, you must use the method **g:Writeln("<tikz instruction>")**, with the constraint that **the backslashes must be doubled**, and without forgetting that the graphic coordinates of a point in  $g$  are not the same for tikz. For example:

```
1 g:Writeln("\\draw" .. g:Coord(Z(1,-1)) .. " node[red] {Text};")
```

Or to change styles:

```
1 g:Writeln("\\tikzset{every node/.style={fill=white}}")
```

In a Beamer presentation, this can also be used to insert pauses in a graph:

```
1 g:Writeln("\\pause")
```

## II Graphics Methods

Polygonal lines, curves, paths, points, and labels can be created.

### 1) Polygonal Lines

**A polygonal line is a list (table) of connected components, and a connected component is a list (table) of complex numbers that represent the affixes of the points.** For example, the instruction:

```
1 local L = { {Z(-4,0), Z(0,2), Z(1,3)}, {Z(0,0), Z(4,-2), Z(1,-1)} }
```

creates a polygonal line with two components in a variable  $L$ .

**Drawing a polygonal line.** This is the **g:Dpolyline(L,close,draw\_options,clip)** method (where  $g$  denotes the graphic being created),  $L$  is a polygonal line, *close* is an optional argument equal to *true* or *false* indicating whether the line should be closed or not (*false* by default), and *draw\_options* is a string that will be passed directly to the `\draw` instruction in the export. The argument *clip* must contain either *nil* (default value) or a table of the form  $\{x_1, x_2, y_1, y_2\}$ , in the first case the line is clipped by the current 2d window **after** its transformation by the 2d matrix of the graph, in the second case the line is clipped by the window  $[x_1, x_2] \times [y_1, y_2]$  **before** being transformed by the graph matrix.

**Choosing options for drawing a polygonal line.** Drawing options can be passed directly to the `\draw` instruction in the export, but they will have only a local effect. These options can be modified globally using the:

**g:Lineoptions(style,color,width,arrows)**

method (when one of the arguments is nil, its default value is used):

- *color* is a string representing a color known to tikz (default is black),
- *style* is a string representing the type of line to draw. This style can be:
  - *"noline"*: undrawn line,
  - *"solid"*: solid line (default value),
  - *"dotted"*: dotted line,

- “*dashed*”: dashed line,
- custom style: the *style* argument can be a string of the form (example): “{2.5pt}{2pt}” which means: a 2.5pt line followed by a 2pt space, the number of values can be greater than 2, e.g.: “{2.5pt}{2pt}{1pt}{2pt}” (succession of on, off).
- *width* is a number representing the line thickness expressed in tenths of a point, for example 8 for an actual thickness of 0.8pt (default value of 4),
- *arrows* is a string that specifies the type of arrow that will be drawn, this can be:
  - “-” which means no arrow (default value),
  - “->” which means an arrow at the end,
  - “<-” which means an arrow at the beginning,
  - “<->” which means an arrow at each end.

**WARNING:** The arrow is not drawn when the argument *close* is true.

The options can be modified individually using the following methods:

- **g:Linecolor(color)**,
- **g:Linestyle(style)**,
- **g:Linewidth(width)**,
- **g:Arrows(arrows)**,
- plus the following methods:
  - **g:Lineopacity(opacity)**, which sets the opacity of the line drawing. The *opacity* argument must be a value between 0 (fully transparent) and 1 (fully opaque). The default value is 1.
  - **g:Linecap(style)**, to adjust the line ends, the *style* argument is a string that can be:
    - \* “*butt*” (straight end at the breakpoint, default value),
    - \* “*round*” (rounded semicircle end),
    - \* “*square*” (rounded square end).
  - **g:Linejoin(style)**, to adjust the join between segments, the *style* argument is a string that can be:
    - \* “*miter*” (pointed corner, default value),
    - \* “*round*” (or rounded corner),
    - \* “*bevel*” (cut corner).

**Polygonal line fill options.** This is the **g:Filloptions(style,color,opacity,evenodd)** method (which uses the *tikz patterns* library, which is loaded with the package). When one of the arguments is *nil*, its default value is used:

- *color* is a string representing a color known to *tikz* (default is black).
- *style* is a string representing the fill type. This style can be:
  - “*none*”: no fill, this is the default value,
  - “*full*”: full fill,
  - “*bdiag*”: descending hatching from left to right,
  - “*fdiag*”: ascending hatching from left to right,
  - “*horizontal*”: horizontal hatching,
  - “*vertical*”: vertical hatching,
  - “*hvcross*”: horizontal and vertical hatching,

- “diagcross”: descending and ascending diagonals,
- “gradient”: in this case, the fill is done with a gradient defined with the method **g:Gradstyle(string)**, this style is passed as is to the `\draw` instruction. By default, the string defining the gradient style is “left color = white, right color = red”.

Any other style known from the *patterns* library is also possible.

Some options can be modified individually with the methods:

- **g:Fillopacity(opacity)**,
- **g:Filleo(evenodd)**.

```

1 \begin{luadraw}{name=champ}
2 local g = graph:new{window={-5,5,-5,5},bg="Cyan!30",size={10,10}}
3 local f = function(x,y) -- eq. diff. y' = 1-x*y^2=f(x,y)
4     return 1-x*y^2
5 end
6 local A = Z(-1,1) -- A = -1+i
7 local deltaX, deltaY, long = 0.5, 0.5, 0.4
8 local champ = function(f)
9     local vecteurs, v = {}
10    for y = g:Yinf(), g:Ysup(), deltaY do
11        for x = g:Xinf(), g:Xsup(), deltaX do
12            v = Z(1,f(x,y)) -- coordonnées 1 et f(x,y)
13            v = v/cpx.abs(v)*long -- normalisation de v
14            table.insert(vecteurs, {Z(x,y), Z(x,y)+v} )
15        end
16    end
17    return vecteurs -- vecteurs est une ligne polygonale
18 end
19 g:Daxes( {0,1,1}, {labelpos={"none","none"}, arrows="->" } )
20 g:Dpolyline( champ(f), "->,blue" )
21 g:Dodesolve(f, A.re, A.im, {t={-2.75,5},draw_options="red,line width=0.8pt"})
22 g:Dlabeldot("$A$", A, {pos="S"})
23 g:Show()
24 \end{luadraw}

```

Figure 2: Vector field, integral curve of  $y' = 1 - xy^2$

## 2) Segments and Lines

A segment is a list (table) of two complex numbers representing the endpoints. A line is a list (table) of two complex numbers, the first representing a point on the line, and the second a direction vector of the line (this must be non-zero).

### Dangle

- The **g:Dangle(B,A,C,r,draw\_options)** method draws the angle  $BAC$  with a parallelogram (only two sides are drawn). The optional argument  $r$  specifies the length of one side (0.25 by default). The argument *draw\_options* is a string (empty by default) that will be passed as is to the `\draw` instruction.
- The function **angled(B,A,C,r)** returns the list of points of this angle.

### Dbissec

- The method **g:Dbissec(B,A,C,interior,draw\_options)** draws a bisector of the geometric angle  $BAC$ , interior if the optional argument *interior* is *true* (default value), exterior otherwise. The argument *draw\_options* is a string (empty by default) that will be passed as is to the instruction `\draw`.
- The function **bissec(B,A,C,interior)** returns this bisector as a list  $\{A,u\}$  where  $u$  is a direction vector of the line.

### Dhline

The method **g:Dhline(d,draw\_options)** draws a half-line. The argument  $d$  must be a list of complex  $\{A,B\}$  variables. The half-line  $[A,B)$  is drawn.

Variant: **g:Dhline(A,B,draw\_options)**. The argument *draw\_options* is a string (empty by default) that will be passed as is to the `\draw` instruction.

### Dline

The **g:Dline(d,draw\_options)** method draws the line  $d$ , which is a list of type  $\{A,u\}$  where  $A$  represents a point on the line (a complex) and  $u$  a direction vector (a non-zero complex).

Variant: the **g:Dline(A,B,draw\_options)** method draws the line passing through the points  $A$  and  $B$  (two complex numbers). The argument *draw\_options* is a string (empty by default) that will be passed as is to the `\draw` instruction.

### DlineEq

- The **g:DlineEq(a,b,c,draw\_options)** method draws the line with the equation  $ax + by + c = 0$ . The *draw\_options* argument is a string (empty by default) that will be passed as is to the `\draw` instruction.
- The **lineEq(a,b,c)** function returns the line with the equation  $ax + by + c = 0$  as a list  $\{A,u\}$  where  $A$  is a point on the line and  $u$  is a direction vector.

### Dmarkarc

The method **g:Dmarkarc(b,a,c,r,n,long,space,draw\_options)** marks the arc of a circle with center  $a$ , radius  $r$ , extending from  $b$  to  $c$ , with  $n$  small segments. By default, the length (argument *long*) is 0.25, and the spacing (argument *space*) is 0.0625. The argument *draw\_options* is a string (empty by default) that will be passed as is to the instruction `\draw`.

### Dmarkseg

The method **g:Dmarkseg(a,b,n,long,space,angle,draw\_options)** marks the segment defined by  $a$  and  $b$  with  $n$  small segments inclined at *angle* degrees ( $45^\circ$  by default). By default, the length (argument *long*) is 0.25, and the spacing (argument *space*) is 0.125. The argument *draw\_options* is a string (empty by default) that will be passed as is to the instruction `\draw`.

**Dmed**

- The **g:Dmed(A,B,draw\_options)** method draws the perpendicular bisector of the segment  $[A;B]$ .  
Variant: **g:Dmed(seg,draw\_options)** where *segment* is a list of two points representing the segment. The *draw\_options* argument is a string (empty by default) that will be passed as is to the `\draw` instruction.
- The function **med(A,B)** (or **med(seg)**) returns the perpendicular bisector of the segment  $[A,B]$  as a list  $\{C,u\}$  where  $C$  is a point on the line and  $u$  is a direction vector.

**Dparallel**

- The method **g:Dparallel(d,A,draw\_options)** draws the parallel to  $d$  passing through  $A$ . The argument  $d$  can be either a line (a list consisting of a point and a direction vector) or a non-zero vector. The argument *draw\_options* is a string (empty by default) that will be passed as is to the instruction `\draw`.
- The function **parallel(d,A)** returns the parallel to  $d$  passing through  $A$  as a list  $\{B,u\}$  where  $B$  is a point on the line and  $u$  is a direction vector.

**Dperp**

- The method **g:Dperp(d,A,draw\_options)** draws the perpendicular to  $d$  passing through  $A$ . The argument  $d$  can be either a line (a list consisting of a point and a direction vector) or a non-zero vector. The argument *draw\_options* is a string (empty by default) that will be passed as is to the instruction `\draw`.
- The function **perp(d,A)** returns the perpendicular to  $d$  passing through  $A$  as a list  $\{B,u\}$  where  $B$  is a point on the line and  $u$  is a direction vector.

**Dseg**

The **g:Dseg(seg,scale,draw\_options)** method draws the segment defined by the *seg* argument, which must be a list of two complex numbers. The optional *scale* argument (1 by default) is a number that allows you to increase or decrease the segment length (the natural length is multiplied by *scale*). The *draw\_options* argument is a string (empty by default) that will be passed as is to the `\draw` instruction.

**Dtangent**

- The **g:Dtangent(p,t0,long,draw\_options)** method draws the tangent to the curve parameterized by  $p : t \rightarrow p(t)$  (with complex values), at the parameter point  $t_0$ . If the argument *long* is *nil* (the default value), then the entire line is drawn; otherwise, it is a segment of length *long*. The argument *draw\_options* is a string (empty by default) that will be passed as is to the `\draw` instruction.
- The function **tangent(p,t0,long)** returns either the line or a segment (depending on whether *long* is *nil* or not).

**DtangentC**

- The method **g:DtangentC(f,x0,long,draw\_options)** draws the tangent to the Cartesian curve with equation  $y = f(x)$ , at the abscissa point  $x_0$ . If the argument *long* is *nil* (the default value), then the entire line is drawn; otherwise, it is a segment of length *long*. The argument *draw\_options* is a string (empty by default) that will be passed as is to the instruction `\draw`.
- The function **tangentC(f,x0,long)** returns either the line or a segment (depending on whether *long* is *nil* or not).

**DtangentI**

- The method **g:DtangentI(f,x0,y0,long,draw\_options)** draws the tangent to the implicit curve with equation  $f(x,y) = 0$ , at the assumed point  $(x_0,y_0)$  on the curve. If the argument *long* is *nil* (the default value), then the entire line is drawn; otherwise, it is a segment of length *long*. The argument *draw\_options* is a string (empty by default) that will be passed as is to the instruction `\draw`.

- The function **tangentl(f,x0,y0,long)** returns either the line or a segment (depending on whether *long* is *nil* or not).

### Dtangent\_from

- The method **g:Dtangent\_from(A,p,t1,t2,dp,draw\_options,out)** draws the tangent(s) to the curve parameterized by  $p : t \rightarrow p(t)$  (with complex values) originating from the point  $A$  (a complex number). The arguments  $t1$  and  $t2$  represent the bounds of the search interval. The optional argument  $dp$  is a function representing the derivative of the function  $p$ ; by default, this argument is *nil*, and the derivative of  $p$  is replaced by an approximation. The optional argument  $draw_options$  is a string (empty by default) that will be passed as is to the `\draw` instruction. The optional argument  $out$ , if used, must be the name of a variable. This variable must be an array, and at the end of execution, it will contain the points on the curve for which the tangent passes through  $A$ .
- The function **tangent\_from(A,p,t1,t2,dp)** returns the list of points on the curve parameterized by  $p$ , on the interval  $[t1;t2]$ , for which the tangent passes through  $A$  (a complex number). If there are no points, the function returns an empty list.

```

1  \begin{luadraw}{name=tangent_from}
2  local i, cos, sin, pi = cpx.I, math.cos, math.sin, math.pi
3  local g = graph:new{window={-5,5,-5,5}, size={10,10}}
4  local p1 = function(t) return t+i*(t^2/4-1) end -- parabola
5  local p2 = function(t) return 1/2+i*rotate(2*cos(t)+i*sin(t),15) end -- ellipse
6  local p3 = function(t) return math.sinh(t)+i*math.cosh(t)-i*2 end -- branch of a hyperbola
7  local p4 = function(t) return 2*cos(3*t)*cpx.exp(i*t) end -- other
8  local P = 0.5-1.25*i
9  local draw = function(p,t1,t2)
10     local axis_style = { arrows='-Stealth', legend={'$x$', '$y$'} }
11     local S = {}
12     g:Daxes({0, 1, 1}, axis_style)
13     g:Dparametric(p,{t={t1,t2}}, draw_options="line width=0.8pt, Crimson")
14     g:Dtangent_from(P,p,t1,t2,"blue",S)
15     g:Ddots(S,"Crimson"); g:Ddots(P); g:Dlabel("$A$",P,{pos="S"})
16 end
17 g:Saveattr(); g:Viewport(-5,-0.25,0.25,5); g:Coordsystem(-3,4,-3,4); draw(p1,-4,4); g:Restoreattr()
18 g:Saveattr(); g:Viewport(0.25,5,0.25,5); g:Coordsystem(-3,3,-3,3); draw(p2,-pi,pi); g:Restoreattr()
19 g:Saveattr(); g:Viewport(-5,-0.25,-5,-0.25); g:Coordsystem(-3,4,-3,3); draw(p3,-4,4); g:Restoreattr()
20 g:Saveattr(); g:Viewport(0.25,5,-5,-0.25); g:Coordsystem(-3,3,-3,3); draw(p4,-pi,pi); g:Restoreattr()
21 g:Show()
22 \end{luadraw}

```

Figure 3: Tangents from a point

### Dnormal

- The method **g:Dnormal(p,t0,long,draw\_options)** draws the normal to the curve parameterized by  $p : t \rightarrow p(t)$  (with complex values), at the point parameter  $t0$ . If the argument *long* is *nil* (the default value), then the entire line is drawn; otherwise, it is a segment of length *long*. The argument *draw\_options* is a string (empty by default) that will be passed as is to the instruction `\draw`.
- The function **normal(p,t0,long)** returns either the line or a segment (depending on whether *long* is *nil* or not).

### DnormalC

- The **g:DnormalC(f,x0,long,draw\_options)** method draws the normal to the Cartesian curve with equation  $y = f(x)$ , at the abscissa point  $x0$ . If the argument *long* is *nil* (the default value), then the entire line is drawn; otherwise, it is a segment of length *long*. The argument *draw\_options* is a string (empty by default) that will be passed as is to the `\draw` instruction.
- The function **normalC(f,x0,long)** returns either the line or a segment (depending on whether *long* is *nil* or not).

### DnormalI

- The **g:DnormalI(f,x0,y0,long,draw\_options)** method draws the normal to the implicit curve with equation  $f(x, y) = 0$ , at the assumed point  $(x0, y0)$  on the curve. If the *long* argument is *nil* (the default value), then the entire line is drawn; otherwise, it is a segment of length *long*. The *draw\_options* argument is a string (empty by default) that will be passed as is to the `\draw` instruction.
- The function **normalI(f,x0,y0,long)** returns either a line or a segment (depending on whether *long* is *nil* or not).

```

Figure 4: Symmetric of the orthocenter

### 3) Geometric Figures

#### Darc

- The **g:Darc(B,A,C,r,sens,draw\_options)** method draws an arc of a circle with center  $A$  (complex), radius  $r$ , going from  $B$  (complex) to  $C$  (complex) counterclockwise if the argument  $sens$  is 1, and counterclockwise otherwise. The argument  $draw\_options$  is a string (empty by default) that will be passed as is to the  $\backslash draw$  instruction.
- The **arc(B,A,C,r,sens)** function returns the list of points on this arc (polygonal line).
- The function **arcb(B,A,C,r,sens)** returns this arc as a path (see  $\backslash Dpath$ ) using Bézier curves.

#### Dcircle

- The method **g:Dcircle(c,r,d,draw\_options)** draws a circle. When the argument  $d$  is nil, it is the circle with center  $c$  (complex) and radius  $r$ ; when  $d$  is specified (complex), it is the circle passing through the affix points  $c$ ,  $r$ , and  $d$ .

The argument *draw\_options* is a string (empty by default) that will be passed as is to the instruction `\draw`. Another possible syntax: **g:Dcircle(C,draw\_options)** where  $C=\{c,r,d\}$ .

- The **circle(c,r,d)** function returns the list of points on this circle (polygonal line).
- The **circleb(c,r,d)** function returns this circle as a path (see Dpath) using Bézier curves.

### Dellipse

- The **g:Dellipse(c,rx,ry,inclin,draw\_options)** method draws the ellipse centered at  $c$  (complex). The arguments  $rx$  and  $ry$  specify the two radii (on  $x$  and  $y$ ). The optional argument *inclin* is an angle in degrees that indicates the inclination of the ellipse relative to the  $Ox$  axis (zero by default). The argument *draw\_options* is a string (empty by default) that will be passed as is to the `\draw` instruction.
- The **ellipse(c,rx,ry,inclin)** function returns the list of points on this ellipse (polygonal line).
- The function **ellipseb(c,rx,ry,inclination)** returns this ellipse as a path (see Dpath) using Bézier curves.

### Dellipticarc

- The method **g:Dellipticarc(B,A,C,rx,ry,sens,inclination,draw\_options)** draws an arc of an ellipse centered at  $A$  (complex) and radii at  $rx$  and  $ry$ , making an angle equal to *inclination* with respect to the  $Ox$  axis (zero by default), going from  $B$  (complex) to  $A$  (complex) in the counterclockwise direction if the argument *sens* is 1, and the opposite direction otherwise. The *draw\_options* argument is a string (empty by default) that will be passed as is to the `\draw` instruction.
- The **ellipticarc(B,A,C,rx,ry,sens,inclination)** function returns the list of points of this arc (polygonal line).
- The **ellipticarcb(B,A,C,rx,ry,sens,inclination)** function returns this arc as a path (see Dpath) using Bézier curves.

### Dpolyreg

- The **g:Dpolyreg(vertex1,vertex2,number of points,direction,draw\_options)** or **g:Dpolyreg(center,vertex,number of points,draw\_options)** method draws a regular polygon. The *draw\_options* argument is a string (empty by default) that will be passed as is to the `\draw` instruction.
- The **polyreg(vertex1,vertex2,number of points,direction)** function and the **polyreg(center,vertex,number of points)** function return the list of vertices of this regular polygon.

### Drectangle

- The **g:Drectangle(a,b,c,draw\_options)** method draws a rectangle with consecutive vertices  $a$  and  $b$ , and whose opposite side passes through  $c$ . The *draw\_options* argument is a string (empty by default) that will be passed as is to the `\draw` instruction.
- The **rectangle(a,b,c)** function returns the list of vertices of this rectangle.

### Dsequence

- The **g:Dsequence(f,u0,n,draw\_options)** method draws the "staircases" of the recurrent sequence defined by its first term  $u_0$  and the relation  $u_{k+1} = f(u_k)$ . The argument  $f$  must be a function of a real-valued variable, and the argument  $n$  is the number of terms calculated. The argument *draw\_options* is a string (empty by default) that will be passed as is to the `\draw` instruction.
- The **sequence(f,u0,n)** function returns the list of points constituting these "staircases".

```

1 \begin{luadraw}{name=sequence}
2 local g = graph:new{window={-0.1,1.7,-0.1,1.1},size={10,10,0}}
3 local i, pi, cos = cpx.I, math.pi, math.cos
4 local f = function(x) return cos(x)-x end
5 local ell = solve(f,0,pi/2)[1]
6 local L = sequence(cos,0.2,5) -- u_{n+1}=cos(u_n), u_0=0.2
7 local seg, z = {}, L[1]
8 for k = 2, #L do
9     table.insert(seg,{z,L[k]})
10    z = L[k]
11 end -- seg est la liste des segments de l'escalier
12 g:Writeln("\tikzset{->/.style={decoration={markings, mark=at position #1 with {\arrow{Stealth}}},
13    \postaction={decorate}}}")
14 g:Daxes({0,1,1}, {arrows="-Stealth"})
15 g:DlineEq(1,-1,0,"line width=0.8pt,ForestGreen")
16 g:Dcartesian(cos, {x={0,pi/2},draw_options="line width=1.2pt,Crimson"})
17 g:Dpolyline(seg,false,"->=0.65,blue")
18 g:Dlabel("$u_0$",0.2,{pos="S",node_options="blue"})
19 g:Dseg({ell, ell*(1+i)},1,"dashed,gray")
20 g:Dlabel("$\ell\approx\round(ell,3)..\$", ell,{pos="S"})
21 g:Ddots(ell*(1+i)); g:Labelcolor("Crimson")
22 g:Dlabel("$\mathcal{C}_{\cos}$",Z(1,cos(1)),{pos="E"})
23 g:Dlabel("$y=x$",Z(0.4,0.4),{pos="S",dist=0.1})
24 g:Show()
25 \end{luadraw}

```

Figure 5: Sequence  $u_{n+1} = \cos(u_n)$ 

The **g:Arg(z)** method calculates and returns the *real* argument of the complex  $z$ , that is, its argument (in radians) when exported to the tikz coordinate system (to do this, you must apply the graph's transformation matrix to  $z$ , then convert the coordinate system to that of tikz). If the graph coordinate system is orthonormal and the transformation matrix is the identity matrix, then the result is identical to that of **cpx.arg(z)** (this is not the case in the example above).

Similarly, the **g:Abs(z)** method calculates and returns the *real* modulus of the complex  $z$ , that is, its modulus when exported to the tikz coordinate system; it is therefore a length in centimeters. If the graph coordinate system is orthonormal with 1 cm per unit on each axis, and if the transformation matrix is an isometry, then the result is identical to that of **cpx.abs(z)**.

## Dsquare

- The **g:Dsquare(a,b,sens,draw\_options)** method draws the square with consecutive vertices  $a$  and  $b$ , in the counterclockwise direction when *sens* is 1 (the default value). The argument *draw\_options* is a string (empty by default) that will be passed as is to the `\draw` instruction.
- The **square(a,b,sens)** function returns the list of vertices of this square.

## Dwedge

The method **g:Dwedge(B,A,C,r,sens,draw\_options)** draws an angular sector with center  $A$  (complex), radius  $r$ , going from  $B$  (complex) to  $C$  (complex) counterclockwise if the argument *sens* is 1, and counterclockwise otherwise. The argument *draw\_options* is a string (empty by default) that will be passed as is to the instruction `\draw`.

## 4) Curves

### Parametric: Dparametric

- The function **parametric(p,t1,t2,nbdots,discont,nbdiv)** calculates the points and returns a polygonal line (no drawing).
  - The argument  $p$  is the parameterization; it must be a function of a real variable  $t$  and complex-valued variables, for example: `local p = function(t) return cpx.exp(t*cpx.I) end`
  - The arguments  $t1$  and  $t2$  are required with  $t1 < t2$ ; they form the bounds of the interval for the parameter.
  - The argument *nbdots* is optional; it is the (minimum) number of points to calculate; it is 40 by default.
  - The argument *discont* is an optional Boolean that indicates whether there are discontinuities or not; it is false by default.
  - The argument *nbdiv* is a positive integer that is 5 by default and indicates the number of times the interval between two consecutive values of the parameter can be cut in two (dichotomized) when the corresponding points are too far apart.
- The method **g:Dparametric(p,args)** calculates the points and draws the curve parametrized by  $p$ . The *args* parameter is a 6-field table:

```
{ t={t1,t2}, nbdots=40, discont=true/false, nbdiv=5, draw_options="", clip={x1,x2,y1,y2} }
```

- By default, the  $t$  field is equal to  $\{g:Xinf(),g:Xsup()\}$ ,
- the *nbdots* field is equal to 40,
- the *discont* field is equal to *false*,
- the *nbdiv* field is equal to 5,
- the *draw\_options* field is an empty string (this will be passed as is to the instruction `\draw`),
- the *clip* field is either *nil* (default value) or a table  $\{x1,x2,y1,y2\}$ . In the first case, the line is clipped by the current 2D window **after** its transformation by the graph's 2D matrix. In the second case, the line is clipped by the window  $[x_1, x_2] \times [y_1, y_2]$  **before** being transformed by the graph's matrix.

### Polars: Dpolar

- The function **polar(rho,t1,t2,nbdots,discont,nbdiv)** calculates the points and returns a polygonal line (no drawing). The argument  $\rho$  is the polar parameterization of the curve; it must be a function of a real variable  $t$  and with real values, for example:
 

```
local rho = function(t) return 4*math.cos(2*t) end
```

 The other arguments are identical to those for parameterized curves.
- The method **g:Dpolar(rho,args)** calculates the points and draws the polar curve parameterized by  $\rho$ . The *args* parameter is a 6-field table:

```
{ t={t1,t2}, nbdots=40, discont=true/false, nbdiv=5, draw_options="", clip={x1,x2,y1,y2} }
```

- By default, the  $t$  field is equal to  $\{-\pi, \pi\}$ ,
- the  $nbdots$  field is equal to 40,
- the  $discont$  field is equal to *false*,
- the  $nbdiv$  field is equal to 5,
- the  $draw\_options$  field is an empty string (this will be passed as is to the *\instruction*). *draw*),
- the  $clip$  field is either *nil* (default value) or a table  $\{x1,x2,y1,y2\}$ . In the first case, the line is clipped by the current 2D window **after** its transformation by the graph's 2D matrix; in the second case, the line is clipped by the window  $[x_1, x_2] \times [y_1, y_2]$  **before** being transformed by the graph's matrix.

### Cartesian: Dcartesian

- The function **cartesian(f,x1,x2,nbdots,discont,nbdiv)** calculates the points and returns a polygonal line (no drawing). The argument  $f$  is the function whose curve we want to obtain. It must be a function of a real variable  $x$  and with real values, for example:

```
local f = function(x) return 1+3*math.sin(x)*x end
```

The arguments  $x1$  and  $x2$  are required and form the bounds of the interval for the variable. The other arguments are identical to those for parametric curves.

- The method **g:Dcartesian(f,args)** calculates the points and draws the curve of  $f$ . The  $args$  parameter is a 6-field table:

```
{ x={x1,x2}, nbdots=40, discont=true/false, nbdiv=5, draw_options="", clip={x1,x2,y1,y2} }
```

- By default, the  $x$  field is equal to  $\{g:Xinf(),g:Xsup()\}$ ,
- the  $nbdots$  field is equal to 40,
- the  $discont$  field is equal to *false*,
- the  $nbdiv$  field is equal to 5,
- the  $draw\_options$  field is an empty string (this will be passed as is to the instruction *\draw*),
- the  $clip$  field is either *nil* (default value) or a table  $\{x1,x2,y1,y2\}$ . In the first case, the line is clipped by the current 2D window **after** its transformation by the 2D graph matrix. In the second case, the line is clipped by the window  $[x_1, x_2] \times [y_1, y_2]$  **before** being transformed by the graph matrix.

### Periodic Functions: Dperiodic

- The function **periodic(f,period,x1,x2,nbdots,discont,nbdiv)** calculates the points and returns a polygonal line (no drawing).
  - The argument  $f$  is the function whose curve we want; it must be a function of a real variable  $x$  and with real values.
  - The argument  $period$  is a table of the type  $\{a,b\}$ , with  $a < b$  representing a period of the function  $f$ .
  - The arguments  $x1$  and  $x2$  are required and form the bounds of the interval for the variable.
  - The other arguments are identical to those for parametric curves.
- The method **g:Dperiodic(f,period,args)** calculates the points and draws the curve of  $f$ . The  $args$  parameter is a 6-field table:

```
{ x={x1,x2}, nbdots=40, discont=true/false, nbdiv=5, draw_options="", clip={x1,x2,y1,y2} }
```

- By default, the  $x$  field is equal to  $\{g:Xinf(),g:Xsup()\}$ ,
- the  $nbdots$  field is equal to 40,
- the  $discont$  field is equal to *false*,

- the *nbdiv* field is equal to 5,
- the *draw\_options* field is an empty string (this will be passed as is to the instruction). `\draw`),
- the *clip* field is either *nil* (default value) or a table  $\{x1,x2,y1,y2\}$ . In the first case, the line is clipped by the current 2D window **after** its transformation by the graph's 2D matrix; in the second case, the line is clipped by the window  $[x_1, x_2] \times [y_1, y_2]$  **before** being transformed by the graph's matrix.

### Step Functions: Dstepfunction

- The **stepfunction(def,discont)** function calculates the points and returns a polygonal line (no drawing).

- The *def* argument defines the step function; it is a two-field table:

```
{ {x1,x2,x3,...,xn}, {c1,c2,...} }
```

The first element  $\{x1,x2,x3,...,xn\}$  must be a subdivision of the segment  $[x1, xn]$ .

The second element  $\{c1,c2,...\}$  is the list of constants, with *c1* for the segment  $[x1,x2]$ , *c2* for the segment  $[x2,x3]$ , etc.

- The argument *discont* is a Boolean that defaults to *true*.

- The method **g:Dstepfunction(def,args)** calculates the points and draws the curve of the step function.

- The argument *def* is the same as the one described above (definition of the step function).
- The *args* argument is a three-field table:

```
{ discont=true/false, draw_options="", clip={x1,x2,y1,y2} }
```

By default, the *discont* field is *true*, and the *draw\_options* field is an empty string (this will be passed as is to the `\draw` instruction). The *clip* field is either *nil* (default value) or a table  $\{x1,x2,y1,y2\}$ . In the first case, the line is clipped by the current 2D window **after** its transformation by the graph's 2D matrix. In the second case, the line is clipped by the window  $[x_1, x_2] \times [y_1, y_2]$  **before** being transformed by the graph's matrix.

### Piecewise Affine Functions: Daffinebypiece

- The function **affinebypiece(def,discont)** calculates the points and returns a polygonal line (no drawing).

- The argument *def* defines the step function; it is a two-field table:

```
{ {x1,x2,x3,...,xn}, { {a1,b1}, {a2,b2}, ... } }
```

The first element  $\{x1,x2,x3,...,xn\}$  must be a subdivision of the segment  $[x1, xn]$ .

The second element  $\{ \{a1,b1\}, \{a2,b2\}, ... \}$  means that on  $[x1,x2]$  the function is  $x \mapsto a_1x + b_1$ , on  $[x2,x3]$  the function is  $x \mapsto a_2x + b_2$ , etc.

- The argument *discont* is a boolean that defaults to *true*.

- The method **g:Daffinebypiece(def,args)** calculates the points and draws the curve of the piecewise affine function.

- The argument *def* is the same as the one described above (definition of the piecewise affine function).
- The *args* argument is a 3-field table:

```
{ discont=true/false, draw_options="", clip={x1,x2,y1,y2} }
```

By default, the *discont* field is set to *true*, and the *draw\_options* field is an empty string (this will be passed as is to the `\draw` instruction). The *clip* field is either *nil* (default value) or a table  $\{x1,x2,y1,y2\}$ , in the first case the line is clipped by the current 2d window **after** its transformation by the 2d matrix of the graph, in the second case the line is clipped by the window  $[x_1, x_2] \times [y_1, y_2]$  **before** being transformed by the graph matrix.

**Differential Equations: Dodesolve**

- The function **odesolve(f,t0,Y0,tmin,tmax,nbdots,method)** allows an approximate solution of the differential equation  $Y'(t) = f(t, Y(t))$  in the interval  $[tmin, tmax]$  which must contain  $t0$ , with the initial condition  $Y(t0) = Y0$ .
  - The argument  $f$  is a function  $f : (t, Y) \rightarrow f(t, Y)$  with values in  $R^n$  and where  $Y$  is also in  $R^n$ :  $Y = \{y1, y2, \dots, yn\}$  (when  $n = 1$ ,  $Y$  is a real number).
  - The arguments  $t0$  and  $Y0$  give the initial conditions with  $Y0 = \{y1(t0), \dots, yn(t0)\}$  (the  $y_i$  numbers are real), or  $Y0 = y1(t0)$  when  $n = 1$ .
  - The arguments  $tmin$  and  $tmax$  define the resolution interval; this must contain  $t0$ .
  - The argument  $nbdots$  indicates the number of points calculated on either side of  $t0$ .
  - The optional argument  $method$  is a string that can be *"rkf45"* (default), or *"rk4"*. In the first case, we use the Runge Kutta-Fehlberg method (with variable step size), in the second case, it is the classic Runge-Kutta method of order 4.
  - As output, the function returns the following matrix (list of lists of real numbers):

```
{ {tmin,...,tmax}, {y1(tmin),...,y1(tmax)}, {y2(tmin),...,y2(tmax)},...}
```

The first component is the list of values of  $t$  (in ascending order), the second is the list of (approximate) values of the component  $y1$  corresponding to these values of  $t$ , ... etc.

- The method **g:DplotXY(X,Y,draw\_options,clip)**, where the arguments  $X$  and  $Y$  are two lists of real numbers of the same length, draws the polygonal line consisting of the points  $(X[k], Y[k])$ . The argument  $draw\_options$  is a string (empty by default) that will be passed as is to the `\draw` instruction. The  $clip$  field is either *nil* (default value) or a table  $\{x1, x2, y1, y2\}$ . In the first case, the line is clipped by the current 2D window **after** its transformation by the graph's 2D matrix. In the second case, the line is clipped by the window  $[x_1, x_2] \times [y_1, y_2]$  **before** being transformed by the graph's matrix.

```

Figure 6: A Lokta-Volterra differential system

- The method **g:Dodesolve(f,t0,Y0,args)** allows the drawing of a solution to the equation  $Y'(t) = f(t, Y(t))$ .
  - The required argument  $f$  is a function  $f : (t, Y) \rightarrow f(t, Y)$  with values in  $R^n$  and where  $Y$  is also in  $R^n$ :  $Y = \{y_1, y_2, \dots, y_n\}$  (when  $n = 1$ ,  $Y$  is a real number).
  - The arguments  $t0$  and  $Y0$  give the initial conditions with  $Y0 = \{y_1(t0), \dots, y_n(t0)\}$  (the  $y_i$  are real), or  $Y0 = y_1(t0)$  when  $n = 1$ .
  - The *args* argument (optional) allows you to define the parameters for the curve. It is a table with 6 fields:

```
{ t={tmin,tmax}, out={i1,i2}, nbdots=50, method="rkf45"/"rk4", draw_options="", clip={x1,x2,y1,y2} }
```

- \* The  $t$  field determines the interval for the variable  $t$ . By default, it is  $\{g:Xinf(), g:Xsup()\}$ .
- \* The *out* field is a table of two integers  $\{i1, i2\}$ . If  $M$  denotes the matrix returned by the *odesolve* function, the points drawn will have the  $M[i1]$  as abscissas and the  $M[i2]$  as ordinates. By default, we have  $i1=1$  and  $i2=2$ , which corresponds to the  $y_1$  function as a function of  $t$ .
- \* The *nbdots* field determines the number of points to calculate for the function (50 by default).
- \* The *method* field determines the method to use; possible values are "rkf45" (default value), or "rk4".
- \* The *draw\_options* field is a string (empty by default) that will be passed as is to the *\draw* instruction.
- \* The *clip* field is either *nil* (default value) or a table  $\{x1, x2, y1, y2\}$ . In the first case, the line is clipped by the current 2D window **after** its transformation by the graph's 2D matrix. In the second case, the line is clipped by the window  $[x_1, x_2] \times [y_1, y_2]$  **before** its transformation by the graph's matrix.

### Implicit Curves: Dimplicit

- The function **implicit(f,x1,x2,y1,y2,grid)** calculates and returns a polygonal line constituting the implicit curve with equation  $f(x, y) = 0$  in the box  $[x_1, x_2] \times [y_1, y_2]$ . This box is split according to the parameter *grid*.
  - The required argument  $f$  is a function  $f : (x, y) \rightarrow f(x, y)$  with values in  $R$ .
  - The arguments  $x1, x2, y1, y2$  define the plot window, which will be the  $[x_1, x_2] \times [y_1, y_2]$  box. We must have  $x1 < x2$  and  $y1 < y2$ .
  - The argument *grid* is a table containing two positive integers:  $\{n1, n2\}$ . The first integer indicates the number of subdivisions following  $x$ , and the second the number of subdivisions following  $y$ .

- The **g:Dimplicit(f,args)** method draws the implicit curve of equations  $f(x, y) = 0$ .

- The required argument  $f$  is a function  $f : (x, y) \rightarrow f(x, y)$  with values in  $R$ .
- The argument  $args$  defines the drawing parameters; it is a table with 3 fields:

```
{ view={x1,x2,y1,y2}, grid={n1,n2}, draw_options="" }
```

- \* The *view* field determines the drawing area  $[x_1, x_2] \times [y_1, y_2]$ . By default, we have  $view=\{g:Xinf(), g:Xsup(), g:Yinf(), g:Ysup()\}$ ,
- \* the *grid* field determines the grid, this field defaults to  $\{50, 50\}$ ,
- \* the *draw\_options* field is a string (empty by default) that will be passed as is to the `\draw` instruction.

### Contour Lines: Dcontour

The **g:Dcontour(f,z,args)** method draws **contour lines** of the function  $f : (x, y) \rightarrow f(x, y)$  with real values.

- The argument  $z$  (required) is the list of different levels to plot.
- The *args* argument (optional) allows you to define the drawing parameters. It is a 4-field table:

```
{ view={x1,x2,y1,y2}, grid={n1,n2}, colors={"color1","color2",...}, draw_options="" }
```

- The *view* field determines the drawing area  $[x_1, x_2] \times [y_1, y_2]$ . By default, we have  $view=\{g:Xinf(), g:Xsup(), g:Yinf(), g:Ysup()\}$ .
- The *grid* field determines the grid. By default, we have  $grid=\{50, 50\}$ .
- The *colors* field is the list of colors per level. By default, this list is empty and the current drawing color is used.
- The *draw\_options* field is a string (empty by default) that will be passed as is to the `\draw` instruction.

```
1 \begin{luadraw}{name=Dcontour}

Figure 7: Example with Dcontour

### Parameterization of a Polygonal Line: *curvilinear\_param*

Let  $L$  be a list of complex numbers representing a continuous "line". It is possible to obtain a parameterization of this line based on a parameter  $t$  between 0 and 1 ( $t$  is the curvilinear abscissa divided by the total length of  $L$ ).

The function **curvilinear\_param**( $L$ ,  $close$ ) returns a function of one variable  $t \in [0; 1]$  and values on the line  $L$  (complex numbers). The value at  $t = 0$  is the first point of  $L$ , and the value at  $t = 1$  is the last point; this function is followed by a number representing the total length of  $L$ . The optional argument  $close$  indicates whether the line  $L$  should be closed (*false* by default).

```

1 \begin{luadraw}{name=curvilinear_param}
2 local g = graph:new{bbox=false,size={10,10}}
3 local i = cpx.I; g:Linewidth(8)
4 local L = cartesian(math.sin,-5,5)[1]
5 insert(L, {5-2*i, -5-2*i})
6 local f = curvilinear_param(L, true)
7 local I = map(f,linspace(0,1,20)) -- 20 points répartis sur L
8 g:Shift(4*i)
9 g:Lineoptions(nil,"ForestGreen",6); g:Dpolyline(L,true)
10 g:Filloptions("full","white"); g:Ddots(I) -- le premier et le dernier point sont confondus car L est fermée
11
12 -- autre exemple d'utilisation:
13 local nb = 16 --nb arrows
14 local t = linspace(0,1,3*nb+1)
15 g:Shift(-4*i)
16 for k = 0,nb-1 do
17     g:Dparametric(f,{t={t[3*k+1],t[3*k+3]}},nbdots=10,nbdiv=2,draw_options="-stealth"})
18 end
19 g:Show()
20 \end{luadraw}

```

Figure 8: Points distributed on a polygonal line

## 5) Domains related to Cartesian curves

### Ddomain1

- The function **domain1(f,a,b,nbdots,discont,nbdiv)** returns a list of complex numbers that represents the contour of the part of the plane bounded by the curve of the function  $f$  on an interval  $[a; b]$ , the  $Ox$  axis, and the lines  $x = a$ ,  $x = b$ .
- The method **g:Ddomain1(f,args)** draws this contour. The optional *args* argument defines the parameters for the curve. It is a table with 5 fields:

```
{ x={a,b}, nbdots=50, discont=false, nbdiv=5, draw_options="" }
```

- The *x* field determines the study interval; by default, it is  $\{g:Xinf(), g:Xsup()\}$ .
- The *nbdots* field determines the number of points to calculate for the function (50 by default).
- The *discont* field indicates whether or not there are discontinuities for the function (*false* by default).
- The *nbdiv* field is used in the method for calculating the curve points (5 by default).
- The *draw\_options* field is a string (empty by default) that will be passed as is to the *\draw* instruction.

### Ddomain2

- The **domain2(f,g,a,b,nbdots,discont,nbdiv)** function returns a list of complex numbers that represents the contour of the part of the plane bounded by the curve of the function  $f$ , the curve of the function  $g$ , and the lines  $x = a$ ,  $x = b$ .
- The **g:Ddomain2(f,g,args)** method draws this contour. The optional *args* argument allows you to define the parameters for the curves. It is a table with 6 fields:

```
{ x={a,b}, nbdots=50, discont=false, nbdiv=5, draw_options="" }
```

- The *x* field determines the study interval; by default, it is  $\{g:Xinf(), g:Xsup()\}$ .
- The *nbdots* field determines the number of points to calculate for the function (50 by default).
- The *discont* field indicates whether or not there are discontinuities for the function (*false* by default).
- The *nbdiv* field is used in the method for calculating the curve points (5 by default).
- The *draw\_options* field is a string (empty by default) that will be passed as is to the *\draw* instruction.

### Ddomain3

- The **domain3(f,g,a,b,nbdots,discont,nbdiv)** function returns a list of complex numbers that represents the contour of the part of the plane bounded by the curve of the function  $f$  and that of the function  $g$  (searching for intersection points in the interval  $[a; b]$ ).

- The **g:Ddomain3(f,g,args)** method draws this contour. The optional *args* argument defines the parameters for the curve. It is a table with 5 fields:

```
{ x={a,b}, nbdots=50, discont=false, nbdiv=5, draw_options="" }
```

- The *x* field determines the study interval; by default, it is  $\{g:Xinf(), g:Xsup()\}$ .
- The *nbdots* field determines the number of points to calculate for the function (50 by default).
- The *discont* field indicates whether or not there are discontinuities for the function (false by default).
- The *nbdiv* field is used in the curve point calculation method (5 by default).
- The *draw\_options* field is a string (empty by default) that will be passed as is to the `\draw` instruction.

```

1 \begin{luadraw}{name=courbe}
2 local g = graph:new{ window={-5,5,-5,5}, bg="", size={10,10} }
3 local f = function(x) return (x-2)^2-2 end
4 local h = function(x) return 2*math.cos(x-2.5)-2.25 end
5 g:Daxes( {0,1,1},{grid=true,gridstyle="dashed", arrows="->"})
6 g:Filloptions("full","brown",0.3)
7 g:Ddomain1( math.floor, { x={-2.5,3.5} } )
8 g:Filloptions("none","white",1); g:Lineoptions("solid","red",12)
9 g:Dstepfunction( {range(-5,5), range(-5,4)},{draw_options="arrows={Bracket-Bracket[reversed]},shorten >=-2pt"})
10 g:Labelcolor("red")
11 g:Dlabel("Partie entière",Z(-3,3},{node_options="fill=white"})
12 g:Ddomain3(f,h,{draw_options="fill=blue,fill opacity=0.6"})
13 g:Dcartesian(f, {x={0,5}, draw_options="blue"})
14 g:Dcartesian(h, {x={0,5}, draw_options="green"})
15 g:Show()
16 \end{luadraw}

```

Figure 9: Integer part, Ddomain1 and Ddomain3 functions

## 6) Points (Ddots) and Labels (Dlabel)

- The method for drawing one or more points is: **g:Ddots(dots, mark\_options)**.
  - The argument *dots* can be either a single point (i.e., a complex), a list (a table) of complex numbers, or a list of lists of complex numbers. The points are drawn in the current color of the line plot.

- The *mark\_options* argument is an optional string that will be passed as is to the `\draw` instruction (local modifications), for example:

```
"color=green, line width=1.2, scale=0.25"
```

- Two methods to globally modify the appearance of points:
  - \* The **g:Dotstyle(style)** method defines the point style. The *style* argument is a string that defaults to `"*"`. The possible styles are those of the *plotmarks* library.
  - \* The **g:Dotscale(scale)** method allows you to adjust the dot size. The *scale* argument is a positive integer that defaults to 1. It is used to multiply the default dot size. The current line width also affects the dot size. For "solid" dot styles (e.g., the *triangle\** style), the current fill style and color are used by the library.
- The method for placing a label is:

**g:Dlabel(text1, anchor1, args1, text2, anchor2, args2, ...).**

- The arguments *text1*, *text2*, ... are strings; they are the labels.
- The arguments *anchor1*, *anchor2*, ... are complex numbers representing the anchor points of the labels.
- The arguments *args1*, *args2*, ... allow you to locally define the label parameters; they are tables with 4 fields:

```
{ pos=nil, dist=0, dir={dirX,dirY,dep}, node_options="" }
```

- \* The *pos* field indicates the position of the label relative to the anchor point. It can be `"N"` for north, `"NE"` for northeast, `"NW"` for northwest, or `"S"`, `"SE"`, `"SW"`. By default, it is set to *center*, and in this case the label is centered on the anchor point.
- \* The *dist* field is a distance in cm that defaults to 0. It is the distance between the label and its anchor point when *pos* is not equal to *center*.
- \* *dir*=`{dirX,dirY,dep}` is the writing direction. The three values *dirX*, *dirY*, and *dep* are three complex numbers representing three vectors. The first two indicate the writing direction, and the third indicates a translation of the label relative to the anchor point. The vector *dep* is zero by default, and the vector *dirY*, if absent, is equal to the vector *dirX* rotated 90 degrees in the clockwise direction. By default, the *dir* option is equal to the current value of the writing direction.
- \* The *node\_options* argument is a string (empty by default) intended to receive options that will be passed directly to `tikz` in the *node[]* instruction.
- \* The labels are drawn in the current color of the document text, but the color can be changed with the *node\_options* argument, for example, by setting: *node\_options*=`"color=blue"`.

**Warning:** The options chosen for a label also apply to subsequent labels if they are unchanged.

Global options for labels:

- The **g:Labelstyle(position)** method allows you to specify the position of the labels relative to the anchor points. The *position* argument is a string that can be: `"N"` for north, `"NE"` for northeast, `"NW"` for northwest, or `"S"`, `"SE"`, `"SW"`. By default, it is set to *center*, in which case the label is centered on the anchor point.
- The **g:Labelcolor(color)** method allows you to set the color of the labels. The *color* argument is a string representing a color for `tikz`. By default, the argument is an empty string, which represents the current color of the document.
- The **g:Labelangle(angle)** method allows you to specify an angle (in degrees) for rotating the labels around the anchor point. This angle is zero by default.
- The **g:Labelsize(size)** method allows you to manage the size of the labels. The *size* argument is a string that can be: `"tiny"`, or `"scriptsize"`, or `"footnotesize"`, etc. By default, the argument is an empty string, which represents the *normalsize* size.
- The **g:Labeldir(dir)** method allows you to manage the writing direction. The argument *dir* is an table of the form *dir*=`{dirX, dirY, dep}`. The three values *dirX*, *dirY*, and *dep* are three complex numbers representing three vectors. The first two indicate the writing direction, and the third indicates a translation of the label relative to the anchor point. The vector *dep* is zero by default, and the vector *dirY*, if absent, is equal to the vector *dirX* rotated 90 degrees in the clockwise direction. When *dir*=`{}`, this represents the usual writing direction.

- The **g:Dlabeldot(text,anchor,args)** method allows you to place a label and draw the anchor point at the same time.
  - The *text* argument is a string; it is the label.
  - The *anchor* argument is a complex representing the label's anchor point.
  - The *args* argument (optional) allows you to define the label and point parameters; it is a 4-field table:

```
{ pos=nil, dist=0, node_options="", mark_options="" }
```

The fields are identical to those of the *Dlabel* method, plus the *mark\_options* field, which is a string that will be passed as is to the *\draw* instruction when drawing the anchor point.

## 7) Paths: Dpath, Dspline, and Dtcurve

- The **path( path )** function returns a polygonal line containing the points constituting the *path*. The optional argument, *nbdots*, is the minimum number of points calculated for each Bézier curve; its default value is the global variable *bezier\_nbdots*, which is initialized to 8.

The *path* is a table of complex numbers and string instructions, for example:

```
{ Z(-3,2),-3,-2,"l",0,2,2,-1,"ca",3,Z(3,3),0.5,"la",1,Z(-1,5),Z(-3,2),"b" }
```

with:

- “*m*” for moveto,
  - “*l*” for lineto,
  - “*b*” for Bezier (two control points are required),
  - “*s*” for a natural cubic spline passing through the points listed,
  - “*c*” for circle (one point and the center, or three points are required),
  - “*ca*” for a circular arc (requires 3 points, a radius, and a direction),
  - “*ea*” for an elliptical arc (requires 3 points, a radius rx, a radius ry, a direction, and possibly an inclination in degrees),
  - “*e*” for an ellipse (requires a point, the center, a radius rx, a radius ry, and possibly an inclination in degrees),
  - “*cl*” for close (closes the current component),
  - “*la*” for a line arc, i.e., a line with rounded corners (the radius must be specified just before the “*la*” instruction),
  - “*cla*” for a closed line with rounded corners (the radius must be specified just before the “*cla*” instruction).
- The **g:Dpath(path,draw\_options)** method draws the *path* (using Bézier curves as much as possible, including arcs, ellipses, etc.). The *draw\_options* argument is a string that will be passed directly to the *\draw* instruction.
    - The *path* argument was described above.
    - The *draw\_options* argument is a string (empty by default) that will be passed as is to the *\draw* instruction.
  - The function **spline(points,v1,v2)** returns a path (to be drawn with Dpath) of the cubic spline passing through the points of the argument *points* (which must be a list of complex vectors). The arguments *v1* and *v2* are tangent vectors imposed at the ends (constraints); when these are equal to *nil*, a natural cubic spline (i.e., unconstrained) is calculated.
  - The method **g:Dspline(points,v1,v2,draw\_options)** draws the spline described above. The argument *draw\_options* is a string that will be passed directly to the instruction *\draw*.

```
1 \begin{luadraw}{name=path_spline}
2 local g = graph:new{window={-5,5,-5,5},size={10,10},bg="Beige"}
3 local i = cpx.I
4 local p = {-3+2*i,-3,-2,"l",0,2,2,-1,"ca",3,3+3*i,0.5,"la",1,-1+5*i,-3+2*i,"b",-1,"m",0,"c"}
5 g:Daxes( {0,1,1} )
6 g:Filloptions("full","blue!30",1,true); g:Dpath(p,"line width=0.8pt")
7 g:Filloptions("none")
8 local A,B,C,D,E = -4-i,-3*i,4,3+4*i,-4+2*i
```

```

9 | g:Lineoptions(nil,"ForestGreen",12); g:Dspline({A,B,C,D,E},nil,-5*i) -- contrainte en E
10 | g:Ddots({A,B,C,D,E},"fill=white,scale=1.25")
11 | g:Show()
12 | \end{luadraw}

```

Figure 10: Path and Spline

- The function **tcurve**(**L**) returns a curve passing through given points as a path, with tangent vectors (left and right) imposed at each point. **L** is a table of the form:

```

1 | L = {point1,{t1,a1,t2,a2}, point2,{t1,a1,t2,a2}, ..., pointN,{t1,a1,t2,a2}}

```

*point1*, ..., *pointN* are the interpolation points of the curve (affixes), and each of them is followed by a table of the form  $\{t1, a1, t2, a2\}$  which specifies the tangent vectors to the curve to the left of the point (with *t1* and *a1*) and to the right of the point (with *t2* and *a2*). The left tangent vector is given by the formula  $V_g = t_1 \times e^{ia_1\pi/180}$ , so *t1* represents the modulus and *a1* is an argument **in degrees** of this vector. The same is true for *t2* and *a2* for the right tangent vector, **but these are optional**, and if not specified, they take the same values as *t1* and *a1*.

Two consecutive points will be connected by a Bézier curve; the function calculates the control points to obtain the desired tangent vectors.

- The method **g:Dtcurve(L,options)** draws the path obtained by **tcurve** described above. The argument *options* is a two-field table:
  - *showdots=true/false* (false by default). This option allows you to draw the given interpolation points as well as the calculated control points, allowing for visualization of the constraints.
  - *draw\_options=""*. This is a string that will be passed directly to the **\draw** instruction.

```

1 | \begin{luadraw}{name=tcurve}
2 | local g = graph:new{window={-0.5,10.5,-0.5,6.5},size={10,10,0}}
3 | local i = cpx.I
4 | local L = {
5 |   1+4*i,{2,-20},
6 |   2+3*i,{2,-70},
7 |   4+i/2,{3,0},
8 |   6+3*i,{4,15},
9 |   8+6*i,{4,0,4,-90}, -- point anguleux
10 | 10+i,{3,-15}}

```

```

11 g:Dgrid({0,10+6*i},{gridstyle="dashed"})
12 g:Daxes(nil,{limits={{0,10},{0,6}},originpos={"center","center"}, arrows="->"})
13 g:Dtcurve(L,{showdots=true,draw_options="line width=0.8pt,red"})
14 g:Show()
15 \end{luadraw}

```

Figure 11: Interpolation curve with imposed tangent vectors

## 8) Paths and Clipping: Beginclip() and Endclip()

A path can be used for clipping using two functions: **g:Beginclip(path,reverse)** and **g:Endclip()**. The first opens a *scope* group and passes the *path* as an argument to tikz's `\clip` function. The second closes the *scope* group; it is essential (otherwise there will be a compilation error). The *reverse* argument is a Boolean that defaults to *false*. When it has the value *true*, the clipping is reversed, meaning that only what is outside the *path* will be drawn, but for this to happen, the path must be counterclockwise.

```

1 \begin{luadraw}{name=polygon_with_different_line_color_and_rounded_corners}
2 local g = graph:new{window={-5,5,-5,5},size={10,10}}
3 local i = cpx.I
4 local Dcolored_polyreg = function(c,a,nb,r,wd,colors)
5   -- c=center, a=vertice, nb=number of sides, r=radius, wd=width in point, colors=list of colors
6   local L = polyreg(c,a,nb)
7   insert(L,{r,"cla"}) --polygon width rounded corners (radius=r)
8   local angle = 360/nb
9   local b = a
10  for k = 1, nb do
11    a = b; b = rotate(a,angle,c)
12    g:Beginclip({2*a-c,c,2*b-c,"l"}) -- définition d'un secteur angulaire pour clipper
13    g:Dpath(L,"line width="..wd.."pt,color="..colors[k])
14    g:Endclip()
15  end
16 end
17 Dcolored_polyreg(3+2*i,5+2*i,5,0.8,12,{"red","blue","orange","green","yellow"}) -- pentagon
18 Dcolored_polyreg(-2.5-2*i,-5-2*i,7,1,24,getpalette(palGasFlame,7)) -- heptagon
19 g:Show()
20 \end{luadraw}

```

Figure 12: Clipping Example

## 9) Axes and Grids

Global variables used for axes and grids:

- $maxGrad = 100$ : Maximum number of tick marks on an axis.
- $defaultlabelshift = 0.125$ : When a grid is drawn with the axes (option  $grid=true$ ), the labels are automatically shifted along the axis using this variable.
- $defaultxylabsep = 0$ : Sets the default distance between labels and tick marks.
- $defaultlegendsep = 0.2$ : Sets the default distance between the legend and the axis.
- $digits = 4$ : Default number of decimal places in string conversions; terminal 0s are removed.
- $dollar = true$ : to add dollars around the tick labels.
- $siunitx = false$ : with the value *true*, the labels are formatted with the macro `\num{. .}` of the *siunitx* package, which allows you to use certain options of this package, such as replacing the decimal point with a comma by doing:

```
\usepackage[local=FR]{siunitx}
```

or by doing:

```
\usepackage{siunitx}
\sisetup{output-decimal-marker={,}}
```

For axes, in both 2D and 3D, all labels are formatted as strings with the **num(x)** function. This transforms the number  $x$  into a string  $str$  with the number of decimal places set by the global variable  $digits$ . When the  $siunitx$  variable has the value *true*, the function returns `"\num{str}"`, otherwise it simply returns  $str$ . This also applies to 3D axes. Here is the code for this function:

```
1 function num(x) -- x is a real, returns a string
2 local rep = strReal(x) -- conversion to string with digits decimals max
3 if siunitx then rep = "\num{"..rep.."}" end --needs \usepackage{siunitx}
4 return rep
5 end
```

## Daxes

The axes are plotted using the method `g:Daxes( {A,xpas,ypas}, options)`.

- The first argument specifies the intersection point of the two axes (this is the complex  $A$ ), the graduation spacing on the  $Ox$  axis (this is  $xpas$ ), and the graduation spacing on  $Oy$  (this is  $ypas$ ). By default, the point  $A$  is the origin  $Z(0,0)$ , and both spacings are equal to 1.
- The argument *options* is a table specifying the possible options. Here are these options with their default values:
  - `showaxe=1,1`. This option specifies whether or not the axes should be plotted (1 or 0). The first value is for the  $Ox$  axis and the second for the  $Oy$  axis.
  - `arrows="-"`. This option allows you to add an arrow to the axes (no arrow by default; enter `"->"` to add an arrow).
  - `limits="auto","auto"`. This option specifies the extent of the two axes (first value for  $Ox$ , second value for  $Oy$ ). The value `"auto"` means that it is the entire line, but you can specify the extreme abscissas, for example: `optlimits=-4,4,"auto"`.
  - `gradlimits={"auto","auto"}`. This option allows you to specify the range of the graduations on both axes (first value for  $Ox$ , second value for  $Oy$ ). The value `"auto"` means that it is the entire line, but you can specify the extreme graduations, for example: `gradlimits={{-4.4},{-2.3}}`.
  - `unit={"",""}`. This option allows you to specify the range of the graduations on the axes. The default value `("")` means that the step value should be taken ( $xstep$  on  $Ox$ , or  $ystep$  on  $Oy$ ), EXCEPT when the option `labeltext` is not the empty string, in which case *unit* takes the value 1.
  - `nbsubdiv={0,0}`. This option specifies the number of subdivisions between two main ticks on the axis.
  - `tickpos={0.5,0.5}`. This option specifies the position of the ticks relative to each axis. These are two numbers between 0 and 1. The default value of 0.5 means they are centered on the axis. (0 and 1 represent the ends).
  - `tickdir={"auto","auto"}`. This option specifies the direction of the ticks on the axis. This direction is a non-zero (complex) vector. The default value `"auto"` means the ticks are orthogonal to the axis.
  - `xyticks={0.2,0.2}`. This option specifies the length of the ticks on the axis.
  - `xylabelsep={0,0}`. This option specifies the distance between the labels and the tick marks on the axis.
  - `originpos={"right","top"}`. This option specifies the position of the label at the origin on the axis. Possible values are: `"none"`, `"center"`, `"left"`, `"right"` for  $Ox$ , and `"none"`, `"center"`, `"bottom"`, `"top"` for  $Oy$ .
  - `originnum={A.re,A.im}`. This option specifies the tick mark value at the intersection of the axes (tick mark number 0).

The formula that defines the label at tick mark number  $n$  is:  $(\text{originnum} + \text{unit} \cdot n) \text{labeltext} / \text{labelden}$ .

- `originloc=A`. This option specifies the intersection point of the axes.
- `legend={"",""}`. This option allows you to specify a legend for the axis.
- `legendpos={0.975,0.975}`. This option specifies the position (between 0 and 1) of the legend relative to each axis.
- `legendsep={0.2,0.2}`. This option specifies the distance between the legend and the axis. The legend is on the other side of the axis from the graduations.
- `legendangle={"auto","auto"}`. This option specifies the angle (in degrees) that the legend should make for the axis. The default value `"auto"` means that the legend must be parallel to the axis if the `labelstyle` option is also set to `"auto"`, otherwise the legend is horizontal.
- `legendstyle={"auto","auto"}`. Specifies the label style for the legends; with the value `"auto"`, it is determined automatically; otherwise, the following values can be used: `"N"`, `"NW"`, `"W"`, `"SW"`, `"S"`, `"SE"`, `"E"`, `"NE"`.
- `labelpos={"bottom","left"}`. This option specifies the position of the labels relative to the axis. For the  $Ox$  axis, the possible values are: `"none"`, `"bottom"`, or `"top"`, for the  $Oy$  axis it is: `"none"`, `"right"`, or `"left"`.
- `labelden={1,1}`. This option specifies the denominator of the labels (integer) for the axis. The formula that defines the label at graduation number  $n$  is:  $(\text{originnum} + \text{unit} \cdot n) \text{labeltext} / \text{labelden}$ .

- `labeltext={"", ""}`. This option defines the text that will be added to the numerator of the labels for the axis.
- `labelstyle={"S", "W"}`. This option sets the label style for each axis. Possible values are "auto", "N", "NW", "W", "SW", "S", "SE", "E".
- `labelangle={0, 0}`. This option sets the angle of the labels in degrees from the horizontal for each axis.
- `labelcolor={"", ""}`. This option allows you to choose a color for the labels on each axis. The empty string represents the default color.
- `labelshift={0, 0}`. This option allows you to set a systematic offset for the labels on the axis (along axis offset).
- `nbdeci={2, 2}`. This option specifies the number of decimal places for numeric values on the axis.
- `numericFormat={0, 0}`. This option specifies the type of digital display (not yet implemented).
- `myxlabels=""`. This option allows you to impose custom labels on the  $Ox$  axis. When any are present, the value passed to the option must be a list of the type: `{pos1, "text1", pos2, "text2", ...}`. The number *pos1* represents an abscissa in the  $(A, x_{pas})$  coordinate system, which corresponds to the affix point  $A + pos1 * x_{pas}$ .
- `myylabels=""`. This option allows you to impose custom labels on the  $Oy$  axis. When any are present, the value passed to the option must be a list of the type: `{pos1, "text1", pos2, "text2", ...}`. The number *pos1* represents an abscissa in the coordinate system  $(A, i * y_{pas})$ , which corresponds to the affix point  $A + pos1 * y_{pas} * i$ .
- `grid=false`. This option allows you to add a grid or not.
- `drawbox=false`. This option draws the axes as a box; in this case, the graduations are on the left and bottom sides.
- `gridstyle="solid"`. This option sets the line style for the primary grid.
- `subgridstyle="solid"`. This option sets the line style for the secondary grid. A secondary grid appears when there are subdivisions on one of the axes.
- `gridcolor="gray"`. This sets the color of the primary grid.
- `subgridcolor="lightgray"`. This sets the color of the secondary grid.
- `gridwidth=4`. Line thickness of the primary grid (which is 0.4pt).
- `subgridwidth=2`. Line thickness of the secondary grid (which is 0.2pt).

```

1 \begin{luadraw}{name=axes_grid}
2 local g = graph:new{window={-6.5,6.5,-3.5,3.5}, size={10,10,0}}
3 local i, pi, a = cpx.I, math.pi, math.sqrt(2)

```

Figure 13: Example with axes with grid

### DaxeX and DaxeY

The methods `g:DaxeX({A,xsteps}, options)` and `g:DaxeY({A,ysteps}, options)` allow you to plot the axes separately.

- The first argument specifies the point serving as the origin (the complex  $A$ ) and the step size of the tick marks on the axis. By default, the point  $A$  is the origin  $Z(0,0)$ , and the step size is equal to 1.
- The argument *options* is a table specifying the possible options. Here are these options with their default values:
  - `showaxe=1`. This option specifies whether or not the axis should be plotted (1 or 0).
  - `arrows="-"`. This option allows you to add an arrow to the axis (no arrow by default; enter `"->"` to add an arrow).
  - `limits="auto"`. This option allows you to specify the range of the two axes. The value "auto" means that it is the entire line, but you can specify the extreme abscissas, for example: `limits={-4.4}`.
  - `gradlimits="auto"`. This option allows you to specify the range of the graduations on both axes. The value "auto" means that it is the entire line, but you can specify the extreme graduations, for example: `gradlimits={-2.3}`.
  - `unit=""`. This option allows you to specify the range of the graduations on the axis. The default value ("") means to take the step value, EXCEPT when the `labeltext` option is not the empty string, in which case *unit* takes the value 1.
  - `nbsubdiv=0`. This option specifies the number of subdivisions between two main tick marks.
  - `tickpos=0.5`. This option specifies the position of the tick marks relative to the axis. These are two numbers between 0 and 1. The default value of 0.5 means they are centered on the axis. (0 and 1 represent the ends).
  - `tickdir="auto"`. This option indicates the direction of the tick marks on the axis. This direction is a non-zero (complex) vector. The default value "auto" means the tick marks are orthogonal to the axis.
  - `xyticks=0.2`. This option specifies the length of the tick marks.
  - `xylabsep=0`. This option specifies the distance between the labels and the tick marks.
  - `originpos="center"`. This option specifies the position of the label at the origin on the axis. Possible values are: "none", "center", "left", "right" for  $Ox$ , and "none", "center", "bottom", "top" for  $Oy$ .
  - `originnum=A.re` for  $Ox$  and `originnum=A.im` for  $Oy$ . This option specifies the value of the tick mark at the origin (tick mark number 0).

The formula that defines the label at tick mark number  $n$  is:  $(\text{originnum} + \text{unit} \cdot n) \text{labeltext} / \text{labelden}$ .

- `legend=""`. This option allows you to specify a legend for the axis.
- `legendpos=0.975`. This option specifies the position (between 0 and 1) of the legend relative to the axis.
- `legendsep=0.2`. This option specifies the distance between the legend and the axis. The legend is on the other side of the axis from the graduations.
- `legendangle="auto"`. This option specifies the angle (in degrees) that the legend should make for the axis. The default value "auto" means that the legend must be parallel to the axis if the `labelstyle` option is also set to "auto", otherwise the legend is horizontal.
- `legendstyle="auto"`. Specifies the label style for the legend. With the value "auto", the style is determined automatically; otherwise, the following values can be used: "N", "NW", "W", "SW", "S", "SE", "E", "NE".
- `labelpos="bottom"` for  $Ox$  and `labelpos="left"` for  $Oy$ . This option specifies the position of the labels relative to the axis. For the  $Ox$  axis, the possible values are: "none", "bottom", or "top", for the  $Oy$  axis it is: "none", "right", or "left".
- `labelden=1`. This option specifies the denominator of the labels (integer) for the axis. The formula that defines the label at graduation number  $n$  is:  $(\text{originnum} + \text{unit} \cdot n) \text{labeltext} / \text{labelden}$ .
- `labeltext=""`. This option defines the text that will be added to the numerator of the labels.
- `labelstyle="S"` for  $Ox$  and `labelstyle="W"` for  $Oy$ . This option defines the style of the labels. The possible values are "auto", "N", "NW", "W", "SW", "S", "SE", "E".
- `labelangle=0`. This option sets the angle of the labels in degrees from the horizontal.
- `labelcolor=""`. This option allows you to choose a color for the labels. The empty string represents the current text color.
- `labelshift=0`. This option allows you to set a systematic offset for labels on the axis (along-axis offset).
- `nbdeci=2`. This option specifies the number of decimal places for numeric labels.
- `numericFormat=0`. This option specifies the type of numeric display (not yet implemented).
- `mylabels=""`. This option allows you to impose custom labels. When there are any, the value passed to the option must be a list of the type:  $\{\text{pos1}, \text{"text1"}, \text{pos2}, \text{"text2"}, \dots\}$ . The number  $\text{pos1}$  represents an abscissa in the coordinate system  $(A, x_{\text{pas}})$  for  $Ox$ , or  $(A, y_{\text{pas}} \cdot i)$  for  $Oy$ , which corresponds to the affix point  $A + \text{pos1} \cdot x_{\text{pas}}$  for  $Ox$ , and  $A + \text{pos1} \cdot y_{\text{pas}} \cdot i$  for  $Oy$ .

## Dgradline

The axis plotting methods are based on the method **`g:Dgradline({A,u}, options)`**, where  $\{A,u\}$  represents the line passing through  $A$  (a complex) and directed by the vector  $u$  (a non-zero complex). The pair  $(A,u)$  serves as a reference point on this line (and orients this line), so each point  $M$  on this line has an abscissa  $x$  such that  $M = A + xu$ . This method allows you to draw this graduated line. The argument *options* is a table specifying the possible options, which are (with their default values):

- `showaxe=1`. This option specifies whether or not the axis should be plotted (1 or 0).
- `arrows="-"`. This option allows you to add an arrow to the axis (no arrow by default; enter `"->"` to add an arrow).
- `limits="auto"`. This option allows you to specify the range of the two axes. The value "auto" means that it is the entire line, but you can specify the extreme abscissas, for example: `limits={-4.4}`.
- `gradlimits="auto"`. This option allows you to specify the range of the graduations on both axes. The value "auto" means that it is the entire line, but you can specify the extreme graduations, for example: `gradlimits={-2.3}`.
- `unit=1`. This option allows you to specify the number of graduations on the axis.
- `nbsubdiv=0`. This option specifies the number of subdivisions between two main ticks.
- `tickpos=0.5`. This option specifies the position of the ticks relative to the axis. These are two numbers between 0 and 1. The default value of 0.5 means they are centered on the axis. (0 and 1 represent the ends).

- `tickdir="auto"`. This option specifies the direction of the ticks on the axis. This direction is a non-zero (complex) vector. The default value "auto" means the ticks are orthogonal to the axis.
- `xyticks=0.2`. This option specifies the length of the ticks.
- `xylabelsep=defaultxylabelsep`. This option specifies the distance between the labels and the tick marks. *defaultxylabelsep* is a global variable with a default value of 0.
- `originpos="center"`. This option specifies the position of the label at the origin on the axis. Possible values are: "none", "center", "left", "right".
- `originnum=0`. This option specifies the value of the tick mark at the origin  $A$  (tick mark number 0).  
The formula that defines the label at graduation number  $n$  (at point  $A + nu$ ) is:  **$(\text{originnum} + \text{unit} * n) \text{labeltext} / \text{labelden}$** .
- `legend=""`. This option allows you to specify a legend for the axis.
- `legendpos=0.975`. This option specifies the position (between 0 and 1) of the legend relative to the axis.
- `legendsep=defaultlegendsep`. This option specifies the distance between the legend and the axis. The legend is on the other side of the axis from the graduations; *defaultlegendsep* is a global variable that defaults to 0.2.
- `legendangle="auto"`. This option specifies the angle (in degrees) that the legend should form for the axis. The default value "auto" means that the legend must be parallel to the axis if the *labelstyle* option is also set to "auto", otherwise the legend is horizontal.
- `legendstyle="auto"`. Specifies the label style for the legend. With the value "auto", the style is determined automatically; otherwise, the following values can be used: "N", "NW", "W", "SW", "S", "SE", "E", "NE".
- `labelpos="bottom"`. This option specifies the position of the labels relative to the axis. The possible values are: "none", "bottom", or "top". This position also determines the position of the legend: on the opposite side of the axis.
- `labelden=1`. This option specifies the denominator of the labels (integer) for the axis. The formula that defines the label at graduation number  $n$  is:  **$(\text{originnum} + \text{unit} * n) \text{labeltext} / \text{labelden}$** .
- `labeltext=""`. This option defines the text that will be added to the numerator of the labels.
- `labelstyle="auto"`. This option defines the label style. Possible values are "auto", "N", "NW", "W", "SW", "S", "SE", "E".
- `labelangle=0`. This option defines the angle of the labels in degrees from the horizontal.
- `labelcolor=""`. This option allows you to choose a color for the labels. The empty string represents the current text color.
- `labelshift=0`. This option allows you to define a systematic offset for the labels on the axis (along axis offset).
- `nbdec=2`. This option specifies the number of decimal places for numeric labels.
- `numericFormat=0`. This option specifies the type of numeric display (not yet implemented).
- `mylabels=""`. This option allows you to impose custom labels. When any are present, the value passed to the option must be a list of the type:  $\{x_1, \text{"text1"}, x_2, \text{"text2"}, \dots\}$ . The numbers  $x_1, x_2, \dots$  represent abscissas in the  $(A, u)$  coordinate system.

```

1 \begin{luadraw}{name=gradline}
2 local g = graph:new{window={-5,5,-5,5},size={10,10}}
3 g:Labelsize("footnotesize")
4 local i = cpx.I
5 g:Dgradline({3.25*i,1+i/2}, {limits={-4,4}, legend="Axe", legendpos=0.5, arrows="-stealth"})
6 g:Dgradline({-3,1}, {legend="demo", labeltext="\\pi", labelden=3, unit=2, nbsubdiv=1, arrows="-latex"})
7 g:Dgradline({3-4*i,-1.25+i/5}, {legend="A", labelstyle="N", gradlimits={-1,5}, nbsubdiv=3, unit=1.411, nbdec=3,
8   ↵ arrows="-Latex"})
9 g:Show()
10 \end{luadraw}

```

Figure 14: Examples of numbered lines

## Dgrid

The `g:Dgrid({A,B},options)` method allows you to draw a grid.

- The first argument is mandatory; it specifies the lower-left corner (this is the *A* complex) and the upper-right corner (this is the *B* complex) of the grid.
- The *options* argument is a table specifying the possible options. Here are these options with their default values:
  - `unit={1,1}`. This option defines the units on the axes for the main grid.
  - `gridwidth=4`. This option defines the line thickness of the main grid (0.4pt by default).
  - `gridcolor="gray"`. Grid color of the main grid.
  - `gridstyle="solid"`. Line style for the primary grid.
  - `nbsubdiv=0,0`. Number of subdivisions (for each axis) between two lines of the primary grid. These subdivisions determine the secondary grid.
  - `subgridcolor="lightgray"`. Color of the secondary grid.
  - `subgridwidth=2`. Line thickness of the secondary grid (0.2pt by default).
  - `subgridstyle="solid"`. Line style for the secondary grid.
  - `originloc=A`. Location of the grid origin.

**Example:** It is possible to work in a non-orthogonal coordinate system. Here is an example where the *Ox* axis is retained, but the first bisector becomes the new axis. *Oy*, we modify the graph's transformation matrix. Based on this modification, the affixes represent the coordinates in the new coordinate system.

```

1 \begin{luadraw}{name=axes_non_ortho}
2 local g = graph:new{window={-5.25,5.25,-4,4},size={10,10}}
3 local i, pi = cpx.I, math.pi
4 local f = function(x) return 2*math.sin(x) end
5 g:Setmatrix({0,1,1+i}); g:Labelsize("small")
6 g:Dgrid({-5-4*i,5+4*i},{gridstyle="dashed"})
7 g:Daxes({0,1,1}, {arrows="-Stealth"})
8 g:Lineoptions("solid","ForestGreen",12); g:Dcartesian(f,{x={-5,5}})

```

```

9 g:Dcircle(0,3,"Crimson")
10 g:DlineEq(1,0,3,"Navy") -- droite d'équation x=-3
11 g:Lineoptions("solid","black",8); g:DtangentC(f,pi/2,1.5,"<->")
12 g:Dpolyline({pi/2,pi/2+2*i,2*i},"dotted")
13 g:Ddots(Z(pi/2,2))
14 g:Dlabeldot("$\\frac{\\pi}{2}$",pi/2,{pos="SW"})
15 g:Show()
16 \\end{luadraw}

```

Figure 15: Example of a non-orthogonal coordinate system

## Dgradbox

The **g:Dgradbox**({A,B,xpas,ypas},options) method allows you to draw a graduated box.

- The first argument is mandatory; it specifies the lower-left corner (this is the  $A$  complex) and the upper-right corner (this is the  $B$  complex) of the box, as well as the step on each axis.
- The *options* argument is a table specifying the possible options. These are the same as for the axes, except for some default values. In addition, the following option is added: `title=""`, which allows you to add a title at the top of the box; however, be careful to leave enough space for this.

```

1 \\begin{luadraw}{name=gradbox}
2 local g = graph:new{window={-5,4,-5.5,5},size={10,10}}
3 local i, pi = cpx.I, math.pi
4 local h = function(x) return x^2/2-2 end
5 local f = function(x) return math.sin(3*x)+h(x) end
6 g:Dgradbox({-pi-4*i,pi+4*i,pi/3,1},{grid=true,originloc=0, originnum={0,0},labeltext={"\\pi",""},labelden={3,1},
7 title="\\textbf{Title}",legend={"Legend $x$", "Legend $y$"}})
8 g:Saveattr(); g:Viewport(-pi,pi,-4,4) -- on limite la vue (clip)
9 g:Filloptions("full","blue",0.6); g:Linestyle("noline"); g:Ddomain2(f,h,{x={-pi/2,2*pi/3}})
10 g:Filloptions("none",nil,1); g:Lineoptions("solid",nil,8); g:Dcartesian(h,{x={-pi,pi}, draw_options="DarkBlue"})
11 g:Dcartesian(f,{x={-pi,pi},draw_options="Crimson"})
12 g:Restoreattr()
13 g:Show()
14 \\end{luadraw}

```

Figure 16: Using Dgradbox

## 10) Set Drawings (Venn Diagrams)

### Drawing a Set

The function **set(center,angle,scale)** returns a path representing a set (egg-shaped), with the center being *center* (complex), the argument *angle* representing the inclination (in degrees) of the set's vertical axis (0 by default), and the argument *scale* being a scale factor to modify the size of the set (1 by default). Such a path can be drawn with the method **g:Dpath()**.

```

1 \begin{luadraw}{name=set}
2 local g = graph:new{window={-5.25,5.25,-5,5},size={10,10}}
3 local i = cpx.I
4 local A, B, C = set(i,0), set(-2-i,25), set(2-i,-25)
5 g:Fillopacity(0.3)
6 g:Dpath(A,"fill=orange"); g:Dpath(B,"fill=blue")
7 g:Dpath(C,"fill=green")
8 g:Fillopacity(1)
9 g:Dlabel("$A$",5*i,{pos="N"}, "$B$",-4+3*i,{pos="W"}, "$C$",4+3*i,{pos="E"})
10 g:Show()
11 \end{luadraw}

```

Figure 17: Drawing a Set

### Operations on Sets

Let  $C_1$  and  $C_2$  be two lists of complex numbers representing the contour of two sets (simple closed curves, all in one piece). There are three possible operations:

- The function **cap(C1,C2)** returns a list of complex numbers representing the contour of the intersection of the sets corresponding to  $C_1$  and  $C_2$ .
- The function **cup(C1,C2)** returns a list of complex numbers representing the contour of the union of the sets corresponding to  $C_1$  and  $C_2$ .
- The function **setminus(C1,C2)** returns a list of complex numbers representing the contour of the difference of the sets corresponding to  $C_1$  and  $C_2$  ( $C_1 \setminus C_2$ ).

The result of these operations, being a list of complex numbers, can be drawn with the **g:Dpolyline()** method.

```

1 \begin{luadraw}{name=cap_and_cup}
2 local g = graph:new{window={-5.5,5.5,-5,5},size={10,10}}
3 local i = cpx.I
4 local A, B, C = set(i,0), set(-2-i,25), set(2-i,-25)
5 g:Fillopacity(0.3)
6 g:Dpath(A,"fill=orange"); g:Dpath(B,"fill=blue"); g:Dpath(C,"fill=green")
7 g:Fillopacity(1)
8 local C1, C2, C3 = path(A), path(B), path(C) -- conversion chemin -> liste de complexes
9 local I = cap(cup(C1,C2),C3)
10 g:Linecolor("red"); g:Filloptions("full","white")
11 g:Dpolyline(I,true,"line width=0.8pt,fill opacity=0.8")
12 g:Dlabel("$A$",5*i,{pos="N"}, "$B$",-4+3*i,{pos="W"}, "$C$",4+3*i,{pos="E"},
13 "$A \cup B \cap C$",-i,{pos="NE",node_options="red,draw"})
14 g:Show()
15 \end{luadraw}

```

Figure 18: Set Operations

**NB** : The result is not always satisfactory when the contours become too complex, or when the contours share common sections.

## 11) Color Calculations

In the *luadraw* environment, colors are character strings that must correspond to colors known to tikz. The *xcolor* package is strongly recommended so as not to be limited to basic colors.

To be able to manipulate colors, they have been defined (in the *luadraw\_colors.lua* module) as tables of three components: red, green, blue, each component being a number between 0 and 1, and with their names in the *svgnames* format of the *xcolor* package. For example, we find (among others) the declarations:

```
1 AliceBlue = {0.9412, 0.9725, 1}
2 AntiqueWhite = {0.9804, 0.9216, 0.8431}
3 Aqua = {0.0, 1.0, 1.0}
4 Aquamarine = {0.498, 1.0, 0.8314}
```

You can refer to the *xcolor* documentation for a list of these colors.

To use these in the *luadraw* environment, you can:

- either use them by name if you have declared them in the preamble: `\usepackage[svgnames]{xcolor}`, for example:  
`g:Linecolor("AliceBlue"),`
- or use them with the *luadraw* **rgb()** function, for example: `g:Linecolor(rgb(AliceBlue))`. However, with this *rgb()* function, to change the color locally, you must do the following (example):  
`g:Dpolyline(L, "color=" .. rgb(AliceBlue)), or g:Dpolyline(L, "fill=" .. rgb(AliceBlue))`. Because the *rgb()* function does not return a color name, but a color definition.

### Functions for color management:

- The **rgb(r,g,b)** or **rgb({r,g,b})** function returns the color as a string understandable by tikz in the `color=...` and `fill=...` options. The values of *r*, *g*, and *b* must be between 0 and 1.
- The **hsb(h,s,b,table)** function returns the color as a string understandable by tikz. The *h* (hue) argument must be a number between 0 and 360, the *s* (saturation) argument must be between 0 and 1, and the *b* (brightness) argument must also be between 0 and 1.

The (optional) argument *table* is a boolean (false by default) that indicates whether the result should be returned as a table  $\{r, g, b\}$  or not (by default it is as a string).

- The function **mixcolor(color1,proportion1 color2,proportion1,...,colorN,proportionN)** mixes the colors *color1*, ..., *colorN* in the requested proportions and returns the resulting color as a string understandable by tikz, followed by the same color as a table  $\{r, g, b\}$ . Each color must be a table of three components  $\{r, g, b\}$ .
- The function **palette(colors,pos,table)**: the argument *colors* is a list (table) of colors in the format  $\{r, b, g\}$ , the argument *pos* is a number between 0 and 1, the value 0 corresponds to the first color in the list and the value 1 to the last. The function calculates and returns the color corresponding to the position *pos* in the list by linear interpolation. The (optional) argument *table* is a boolean (false by default) that indicates whether the result should be returned as a table  $\{r, g, b\}$  or not (by default it is as a string).
- The **getpalette(colors,nb,table)** function: the *colors* argument is a list (table) of colors in  $\{r, b, g\}$  format, the *nb* argument indicates the desired number of colors. The function returns a list of *nb* colors evenly distributed in *colors*. The (optional) *table* argument is a boolean (false by default) that indicates whether the colors are returned as  $\{r, g, b\}$  tables or not (by default, they are as strings).
- The **g:Newcolor(name,rghtable)** method allows you to define a new color in the tikz export in rgb format, whose name will be *name* (string). *rghtable* is a table of three components: red, green, blue (between 0 and 1) defining this color.

You can also use all of TikZ's usual color management features.

By default, there are five color palettes.<sup>2</sup>

```

1 \begin{luadraw}{name=palettes}
2 local g = graph:new{window={-5,5,-5,5},bbox=false, border=true}
3 g:Linewidth(1)
4 local Dpalette = function(pal,A,h,L,N,name)
5     local dl = L/N
6     for k = 1, N do
7         local color = palette(pal,(k-1)/(N-1))
8         g:Drectangle(A,A+h,A+h+dl,"color"..color.."",fill="..color")
9         A = A+dl
10    end
11    g:Drectangle(A,A+h,A+h-L); g:Dlabel(name,A+h/2,{pos="E"})
12 end
13 local A, h, dh, L, N = Z(-5,4), Z(0,-1), Z(0,-1.1), 5, 100
14 Dpalette(rainbow,A,h,L,N,"rainbow"); A = A+dh
15 Dpalette(palAutumn,A,h,L,N,"palAutumn"); A = A+dh
16 Dpalette(palGistGray,A,h,L,N,"palGistGray"); A = A+dh
17 Dpalette(palGasFlame,A,h,L,N,"palGasFlame"); A = A+dh
18 Dpalette(palRainbow,A,h,L,N,"palRainbow")
19 g:Show()
20 \end{luadraw}

```

Figure 19: The five default palettes

<sup>2</sup>A palette is a table of colors; these are themselves tables of numbers between 0 and 1 representing the red, green, and blue components.

### III Geometric Constructions

This section groups together functions that construct geometric figures without a corresponding dedicated graphical method.

#### 1) `circumcircle()`, `incircle()`

- The function **`circumcircle(a,b,c)`** (or **`circumcircle({a,b,c})`**), where  $a$ ,  $b$ , and  $c$  are three points (three complex numbers), returns the circumcircle of the triangle formed by these three points, in the form of a sequence:  $C, r$ , where  $C$  is the center of the circle (a complex number), and  $r$  is its radius.
- The function **`incircle3d(a,b,c)`** (or **`incircle3d({a,b,c})`**), where  $a$ ,  $b$ , and  $c$  are three points (three complex numbers), returns the incircle of the triangle formed by these three points, as a sequence:  $C, r$ , where  $C$  is the center of the circle (a complex number), and  $r$  is its radius.

#### 2) `cvx_hull2d()`

The function **`cvx_hull2d(L)`**, where  $L$  is a list of complex numbers, computes and returns a list of complex numbers representing the convex hull of  $L$ .

#### 3) `delaunay()`

The function **`delaunay(L)`** where  $L$  is a list of **distinct** complex numbers, returns a list of triangles (a triangle being a list of three complex numbers) obtained by Delaunay triangulation of the points of  $L$  (the circumcircle of each triangle does not contain any of the other points).

```

1  \begin{luadraw}{name=delaunay}
2  local g = graph3d:new{bbox=false, pictureoptions="scale=2"}
3  local i = cpx.I; g:Linewidth(6)
4  local L = {0.285+1.46*i,1.556-0.142*i,2.344+1.313*i,-2.38+1.218*i,1.548-0.624*i,0.969+1.819*i,
5  ↵ -0.086-2.191*i,-0.477+1.834*i,-0.904+1.322*i,-2.892+0.025*i}
6  local T = delaunay(L)
7  local n = #T
8  local num = 7 -- we choose a triangle
9  local colors = getpalette(palGasFlame,n)
10 for k = 1, n do
11     g:Dpolyline(T[k],true,'fill='..colors[k])
12 end
13 g:Ddots(L)
14 g:Dcircle( {circumcircle(T[num])}, "line width=0.4pt,gray,dashed" )
15 g:Ddots(T[num],"gray")
16 g:Show()
17 \end{luadraw}

```

Figure 20: Delaunay Triangulation

#### 4) voronoi()

The function **voronoi(L, window)**, where  $L$  is a list of distinct complex numbers, determines the Voronoi diagram of the points in the list  $L$ . This function returns a list of elements of the form  $\{A, \text{polygon}\}$ , where  $A$  is a point in the list  $L$ , and  $\text{polygon}$  is a list of complex numbers representing the vertices of the cell associated with  $A$ . Thus, there is one cell for each point in  $L$ . The cell for point  $A$  contains the points in the plane that are closer to  $A$  than to other points in  $L$ . This function uses Delaunay triangulation. The optional argument *window*, which defaults to  $\{-5, 5, -5, 5\}$ , is used to clip Voronoi cells that are unbounded; this window is automatically enlarged if necessary to contain all the points of  $L$  as well as all the centers of the circles circumscribed about the Delaunay triangles (note: this does not change the 2d window of the current graph).

```

1 \begin{luadraw}{name=voronoi}
2 local g = graph:new{ bbox=true, margin={0,0,0,0}, size={10,10}}
3 local i = cpx.I
4 local S = {0.285+1.46*i, 1.556-0.142*i, 2.344+1.313*i, -2.38+1.218*i, 1.548-0.624*i,
5           0.969+1.819*i, -0.086-2.191*i, -0.477+1.834*i, -0.904+1.322*i, -2.892+0.025*i}
6 local V = voronoi(S)
7 local colors = getpalette(rainbow, #V)
8 for k, T in ipairs(V) do
9     local A, polygon = table.unpack(T)
10    g:Dpolyline(polygon, true, "color=white, line width=1.2pt, fill=..colors[k]")
11    g:Ddots(A, "mark=x, white, scale=2, line width=1.2pt") -- A is one of the points of S
12 end
13 g:Dpolyline(delaunay(S), true, "dotted, line width=0.6pt") -- Delaunay triangles
14 g:Show()
15 \end{luadraw}

```

Figure 21: Voronoï diagram

### 5) `line2strip()`

The function `line2strip(L,width,close,ends)` where  $L$  is a list of complex numbers, or a list of lists of complex numbers, returns a path representing a "strip" centered on  $L$  and of width  $width$ . The optional argument *close* is a boolean that indicates whether  $L$  should be closed (*false* by default). The optional argument *ends* is a boolean that indicates whether both ends of the strip should be drawn (*true* by default, except when the argument *close* is *true*).

```

1 \begin{luadraw}{name=line2strip}
2 local g = graph:new{bbox=false, bg="lightgray"}
3 local i = cpx.I; g:Linewidth(8)
4 local p = {-3+3*i,-3,"1",0,3,3,1,"ca", 3+3*i,"1"}
5 g:Setmatrix({-3+3*i,0.5,0.5*i})
6 local L = line2strip(path(p),1,true) -- p is first converted to polyline
7 g:Dpath(L,"Crimson,fill=Gold"); g:Dpath(p,"gray,dashed")
8 g:Dlabel("close=true",i,{})
9 g:Setmatrix({3+3*i,0.5,0.5*i})
10 local L = line2strip(path(p),1,false) -- p is first converted to polyline
11 g:Dpath(L,"Crimson,fill=Gold"); g:Dpath(p,"gray,dashed")
12 g:Dlabel("close=false",i,{})
13 g:Setmatrix({-i,0.5,0.5*i})
14 local L = line2strip(path(p),1,false,false) -- p is first converted to polyline
15 g:Dpath(L,"Crimson,fill=Gold"); g:Dpath(p,"gray,dashed")
16 g:Dlabel("close=false",1.5*i,{}); g:Dlabel("ends=false",0.5*i,{})
17 g:Show()
18 \end{luadraw}

```

Figure 22: Example with *line2strip*

## 6) `parallel_polyline()`

The function `parallel_polyline(L,width,close)` where  $L$  is a list of complex numbers, or a list of lists of complex numbers, returns a polygonal line parallel to  $L$  and located at a "distance" equal to *width*. The argument *width* can be positive or negative to be on one side or the other of  $L$  (this depends on the direction of traversal of  $L$ ). The optional argument *close* is a boolean that indicates whether  $L$  should be closed (*false* by default).

## 7) `sss_triangle()`

The function `sss_triangle(ab,bc,ca)`, where  $ab$ ,  $bc$ , and  $ca$  are three lengths, computes and returns a list of three points (3 complex numbers)  $\{A, B, C\}$  forming the vertices of a direct triangle whose side lengths are the arguments, i.e.,  $AB = ab$ ,  $BC = bc$ , and  $CA = ca$ , when possible. Vertex  $A$  is always the complex 0 and vertex  $B$  is always the complex  $ab$ . This triangle can be drawn with the `g:Dpolyline` method.

## 8) `sas_triangle()`

The function `sas_triangle(ab,alpha,ca)`, where  $ab$  and  $ca$  are two lengths and  $\alpha$  is an angle in degrees, calculates and returns a list of three points (3 complex numbers)  $A, B, C$  forming the vertices of a triangle such that  $AB=ab$ ,  $CA=ca$ , and angle  $(AB, AC)$  has a measure of  $\alpha$ , whenever possible. Vertex  $A$  is always the complex 0 and vertex  $B$  is always the complex  $ab$ . This triangle can be drawn with the `g:Dpolyline` method.

## 9) `asa_triangle()`

The function `asa_triangle(alpha,ab,beta)`, where  $ab$  is a length,  $\alpha$  and  $\beta$  are two angles in degrees, calculates and returns a list of three points (3 complex numbers)  $\{A, B, C\}$  forming the vertices of a triangle such that  $AB = ab$ , such that angle  $(\vec{AB}, \vec{AC})$  has measure  $\alpha$ , and such that angle  $(\vec{BA}, \vec{BC})$  has measure  $\beta$ , whenever possible. Vertex  $A$  is always complex 0 and vertex  $B$  is always complex  $ab$ . This triangle can be drawn using the `g:Dpolyline` method.

```

1 \begin{luadraw}{name=sss_triangles_and_co}
2 local g = graph:new{window={-5,5,-3,5},size={10,10}}
3 g:Labelsize("footnotesize"); g:Linewidth(8)
4 local i = cpx.I
5 local T1 = shift( sss_triangle(4,5,3), 2*i-2)
6 local T2 = shift( sas_triangle(4,60,2), -4-2*i)
7 local T3 = shift( asa_triangle(30,4,50), 0.5-i)
8 g:Dpolyline({T1,T2,T3}, true)
9 g:Linewidth(4)
10 g:Darc(T2[2],T2[1],T2[3],0.5,1,"->")

```

```

11 g:Darc(T3[2],T3[1],T3[3],0.75,1,"->")
12 g:Darc(T3[1],T3[2],T3[3],0.75,-1,"->")
13 g:Dlabel(
14     "$4$", (T1[1]+T1[2])/2, {pos="N"}, "$5$", (T1[2]+T1[3])/2, {pos="NE"}, "$3$", (T1[1]+T1[3])/2, {pos="W"},
15     "$4$", (T2[1]+T2[2])/2, {pos="N"},
16     ↪ "$60^\circ", T2[1]+Zp(0.9,30*deg), {pos="center"}, "$2$", (T2[1]+T2[3])/2, {pos="W"},
17     "$4$", (T3[1]+T3[2])/2, {pos="N"}, "$30^\circ", T3[1]+Zp(1.15,15*deg), {pos="center"},
18     "$50^\circ", T3[2]+Zp(1.15,155*deg), {pos="center"},
19     "sss\_triangle(4,5,3)", (T1[1]+T1[2])/2, {pos="S"}, "sas\_triangle(4,60,2)", (T2[1]+T2[2])/2, {pos="center"},
20     ↪ "asa\_triangle(30,4,50)", (T3[1]+T3[2])/2, {pos="center"},
21 for _,T in ipairs({T1,T2,T3}) do
22     g:Dlabel("$A$",T[1],{pos="SW"}, "$B$",T[2],{pos="SE"}, "$C$",T[3],{pos="N"})
23 end
24 g:Show()
25 \end{luadraw}

```

Figure 23: sss\_triangle, sas\_triangle and asa\_triangle

## IV Computations on Lists

### 1) concat

The function `concat{table1, table2, ...}` concatenates all the tables passed as arguments and returns the resulting table.

- Each argument can be a real number, a complex number, or a table.
- Example: The instruction `concat(1,2,3,{4,5,6},7)` returns the table  $\{1,2,3,4,5,6,7\}$ .

### 2) cut

The function `cut(L,A,before)` cuts  $L$  at the point  $A$ , which is assumed to be located on the line  $L$  ( $L$  is either a list of complex numbers or a polygonal line, i.e., a list of lists of complex numbers). If the argument *before* is *false* (the default value), then the function returns the part before  $A$ , followed by the part after  $A$ ; otherwise, the reverse is true.

### 3) cutpolyline

The function `cutpolyline(L,D,close)` cuts the polygonal line  $L$  with the straight line  $D$ . The argument  $L$  must be a list of complex numbers or a list of lists of complex numbers, the argument  $D$  is a list of the form  $\{A,u\}$  where  $A$  is a complex (point on the line) and  $u$  is a non-zero complex (direction vector of the line). The argument *close* indicates whether the line  $L$  should be closed (false by default). The function returns three things:

- The part of  $L$  that is in the half-plane defined by the line to the "left" of  $u$  (i.e., containing the point  $A + iu$ ) (it is a polygonal line),
- followed by the part of  $L$  that is in the other half-plane (polygonal line),
- followed by the list of intersection points between  $L$  and the line.

```

1 \begin{luadraw}{name=cutpolyline}
2 local g = graph:new{window={-5,5,-5,5}, size={10,10},margin={0,0,0,0}}
3 g:Linewidth(6)
4 local i = cpx.I
5 local P = g:Box2d() -- polygon representing the 2d window
6 local D1, D2, D3 = {0,1+i}, {2.5,-i}, {-3*i,-1-i/4} -- three lines
7 local P1 = cutpolyline(P,D1,true)
8 local P2 = cutpolyline(P,D2,true)
9 local P3 = cutpolyline(P,D3,true)
10 g:Daxes({0,1,1},{grid=true,gridcolor="LightGray",arrows="->",legend={"$x$", "$y$"}})
11 g:Filloptions("horizontal","blue"); g:Dpolyline(P1,true,"draw=none")
12 g:Filloptions("fdiag","red"); g:Dpolyline(P2,true,"draw=none")
13 g:Filloptions("bdiag","green"); g:Dpolyline(P3,true,"draw=none")
14 g:Filloptions("none","black",1)
15 g:Linewidth(8)
16 g:Dline(D1,"blue"); g:Dline(D2,"red"); g:Dline(D3,"green")
17 g:Dlabel(
18     "$x-y\\leqslant 0$", -3-3*i,{pos="N",dir={1+i,-1+i},dist=0.1,node_options="fill=white,fill opacity=0.8"},
19     "$x-2.5\\geqslant 0$", 2.5+i,{dir={-i,1}},
20     "$-\\frac{x}{4}+y+3\\leqslant 0$", -3-15/4*i,{pos="S",dir={1+i/4,i-1/4}}
21 )
22 g:Show()
23 \end{luadraw}

```

Figure 24: Illustrate a linear programming exercise

#### 4) getbounds

- The function **getbounds**( $L$ ) returns the bounds  $xmin$ ,  $xmax$ ,  $ymin$ ,  $ymax$  of the polygonal line  $L$ .
- Example: `local xmin, xmax, ymin, ymax = getbounds(L)` (where  $L$  denotes a polygonal line).

## 5) getdot

The function **getdot(x,L)** returns the point with abscissa  $x$  (real between 0 and 1) along the connected component  $L$  (list of complex numbers). The abscissa 0 corresponds to the first point and the abscissa 1 to the last. More generally,  $x$  corresponds to a percentage of the length of  $L$ .

## 6) insert

The function **insert(table1, table2, pos)** inserts the elements of *table2* into *table1* at position *pos*.

- The argument *table2* can be a real number, a complex number, or a table.
- The argument *table1* must be a variable that designates a table; this will be modified by the function.
- If the argument *pos* is nil, the insertion is performed at the end of *table1*.
- Example: If a variable  $L$  is equal to  $\{1,2,6\}$ , then after the instruction **insert(L, {3,4,5},3)**, the variable  $L$  will be equal to  $\{1,2,3,4,5,6\}$ .

## 7) interCC

The function **interCC(C1,C2)** returns the intersection of circle  $C1$  with circle  $C2$ , where  $C1=\{O1,r1\}$  (circle with center  $O1$  and radius  $r1$ ), and  $C2=\{O2,r2\}$  (circle with center  $O2$  and radius  $r2$ ). The function returns a list containing 1 or 2 points or the entire circle. If the intersection is not empty, it returns nil.

```

1  \begin{luadraw}{name=interCC}
2  local g = graph:new{window={-10,10,-5,5}, margin={0,0,0,0},size={16,8}}
3  local i = cpx.I
4  -- pour le cercle {0,2}
5  g:Saveattr(); g:Viewport(-10,0,-5,5); g:Coordsystem(-4,6,-5,5)
6  local O = -1
7  local C1, I = {0, 2}, 4-i
8  local C2 = {(O+I)/2,cpx.abs(I-O)/2}
9  local rep = interCC(C1,C2) -- points de tangence
10 g:Dcircle(C1,"blue"); g:Dcircle(C2,"dashed")
11 g:Dhline(I,rep[1],"red"); g:Dhline(I,rep[2],"red") --demi- tangentes
12 g:Ddots(rep); g:Ddots({0,I}); g:Dlabel("$I$",I,{pos="SE"},"$O$",0,{pos="W"},
13     "tangentes au cercle issues de $I$",1-5*i,{pos="N"})
14 g:Restoreattr()
15
16 -- pour l'ellipse (E) : {0,3,2}
17 g:Saveattr(); g:Viewport(0,10,-5,5); g:Coordsystem(-4,6,-5,5)
18 local mat = {0,1.5,i} -- cette matrice transforme un cercle {01,2} en l'ellipse (E)
19 local inv_mat = invmatrix(mat) -- matrice inverse
20 local O1, I1 = table.unpack( mtransform({0,I},inv_mat) ) -- antécédents de O et de I
21 C1 = {O1, 2}
22 C2 = {(O1+I1)/2,cpx.abs(I1-O1)/2}
23 rep = interCC(C1,C2) -- points de tangence (tangentes issues de I1)
24 g:Composematrix(mat) -- on applique la matrice pour retrouver l'ellipse, la tangence est conservée
25 g:Dcircle(C1,"blue"); g:Dcircle(C2,"dashed")
26 g:Dhline(I1,rep[1],'red'); g:Dhline(I1,rep[2],"red")
27 g:Ddots(rep); g:Ddots({O1,I1}); g:Dlabel("$I$",I1,{pos="SE"},"$O$",O1,{pos="W"},
28     "tangentes à l'ellipse issues de $I$",1-5*i,{pos="N"})
29 g:Restoreattr()
30 g:Show()
31 \end{luadraw}

```

Figure 25: Tangents to a circle O,2 and to an ellipse O,3,2 from a point

**8) interD**

The function **interD(d1,d2)** returns the intersection point of the lines  $d1$  and  $d2$ . A line is a list of two complex numbers: a point on the line and a direction vector.

**9) interDC**

The function **interDC(d,C)** returns the intersection of the line  $d$  with the circle  $C$ , where  $d=\{A,u\}$  (a line passing through  $A$  and directed by  $u$ ), and  $C=\{O,r\}$  (a circle with center  $O$  and radius  $r$ ). The function returns a list containing 1 or 2 points if the intersection is not empty; otherwise, it returns *nil*.

**10) interDL**

The function **interDL(d,L)** returns the list of intersection points between the straight line  $d$  and the polygonal line  $L$ .

**11) interL**

The function **interL(L1,L2)** returns the list of intersection points of the polygonal lines defined by  $L1$  and  $L2$ . These two arguments are two lists of complex numbers or two lists of lists of complex numbers.

**12) interP**

The function **interP(P1,P2)** returns the list of intersection points of the paths defined by  $P1$  and  $P2$ . These two arguments are two lists of complex numbers and instructions (see *Dpath*).

**13) isobar**

The function **isobar(L)**, where  $L$  is a list of complex numbers, returns the isobarycenter of these numbers. If  $L$  contains elements that are not real or complex numbers, they are ignored.

**14) linspace**

The function **linspace(a,b,nbdots)** returns a list of *nbdots* equally distributed numbers from  $a$  to  $b$ . By default, *nbdots* is 50.

## 15) map

The function **map(f,list)** applies the function  $f$  to each element of the *list* and returns the table of results. When a result is *nil*, the complex *cpx.Jump* is inserted into the list.

## 16) merge

The function **merge(L)** reassembles, if possible, the connected components of  $L$ , which must be a list of lists of complex numbers. The function returns the result.

## 17) polyline2path

The function **polyline2path(L)** where  $L$  is a list of complex numbers or a list of lists of complex numbers, returns  $L$  as a path (which can be drawn with the *g:Dpath()* method).

## 18) range

The function **range(a,b,step)** returns the list of numbers from  $a$  to  $b$  with a step equal to *step*, which is 1 by default.

## 19) Clipping Functions

- The function **clipseg(A,B,xmin,xmax,ymin,ymax)** clips the segment  $[A,B]$  with the window  $[xmin,xmax] \times [ymin,ymax]$  and returns the result.
- The function **clipline(d,xmin,xmax,ymin,ymax)** clips the line  $d$  with the window  $[xmin,xmax] \times [ymin,ymax]$  and returns the result. The line  $d$  is a list of two complex numbers: a point and a direction vector.
- The function **clippolyline(L,xmin,xmax,ymin,ymax,close)** clips the polygonal line  $L$  with  $[xmin,xmax] \times [ymin,ymax]$  and returns the result. The argument  $L$  is a list of complex numbers or a list of lists of complex numbers. The optional argument *close* (false by default) indicates whether the polygonal line should be closed.
- The function **clipdots(L,xmin,xmax,ymin,ymax)** clips the point list  $L$  with the window  $[xmin,xmax] \times [ymin,ymax]$  and returns the result (exterior points are simply excluded). The argument  $L$  is a list of complex numbers or a list of lists of complex numbers.

## 20) Adding Mathematical Functions

In addition to the functions associated with graphics methods that perform calculations and return a polygonal line (such as *cartesian*, *periodic*, *implicit*, *odesolve*, etc.), the *luadraw* package adds some mathematical functions that are not natively provided in the *math* module.

### Protected Evaluation: evalf

The **evalf(f,...)** function allows you to evaluate  $f(\dots)$  and return the result if there is no runtime error in Lua; otherwise, the function returns *nil*. For example, executing:

```
1 local f = function(a,b)
2   return 2*Z(a,1/b)
3 end
4 print(f(1,0))
```

causes the runtime error attempt to perform arithmetic on a nil value (in the console), because here  $Z(1,1/0)$  returns *nil*, and Lua does not accept an argument equal to *nil* in a calculation. On the other hand, executing:

```
1 local f = function(a,b)
2   return 2*Z(a,1/b)
3 end
4 print(evalf(f,1,0))
```

does not cause an error from Lua, and there is no output to the console either since the value to be displayed is *nil*.

**int**

The function **int(f,a,b)** returns an approximate value of the integral of the function  $f$  over the interval  $[a; b]$ . The function  $f$  is a real variable and has real or complex values. The method used is Simpson's method, accelerated twice with the Romberg method.

**Example:**

```
\int_0^1 e^{t^2} \mathrm{d} t \approx \directlua{tex.sprint(int(function(t) return math.exp(t^2) end, 0, 1))}
```

**Result:**  $\int_0^1 e^{t^2} dt \approx 1.4626517459589$ .

**gcd**

The function **gcd(a,b)** returns the greatest common divisor between  $a$  and  $b$ .

**lcm**

The function **lcm(a,b)** returns the smallest positive common divisor between  $a$  and  $b$ .

**solve**

The function **solve(f,a,b,n)** numerically solves the equation  $f(x) = 0$  in the interval  $[a; b]$ , which is subdivided into  $n$  pieces ( $n$  is 25 by default). The function returns a list of results or *nil*. The method used is a Newtonian variant.

**Example 1:**

```
\begin{luacode}
resol = function(f,a,b)
  local y = solve(f,a,b)
  if y == nil then tex.sprint("\emptyset")
  else
    local str = y[1]
    for k = 2, #y do
      str = str..", "..y[k]
    end
    tex.sprint(str)
  end
end
\end{luacode}
\def\solve#1#2#3{\directlua{resol(#1,#2,#3)}}%
\begin{luacode}
f1 = function(x) return math.cos(x)-x end
f2 = function(x) return x^3-2*x^2+1/2 end
\end{luacode}
Solving the equation  $\cos(x)=x$  in  $[0;\frac{\pi}{2}]$  gives  $\text{\solve{f1}\{0\}\{math.pi/2\}}.$ \par
Solving the equation  $\cos(x)=x$  in  $[\frac{\pi}{2};\pi]$  gives  $\text{\solve{f1}\{math.pi/2\}\{math.pi\}}.$ \par
Solving the equation  $x^3-2x^2+\frac{1}{2}=0$  in  $[-1;2]$  gives:  $\text{\solve{f2}\{-1\}\{2\}}.$ 
```

**Result:**

Solving the equation  $\cos(x) = x$  in  $[0; \frac{\pi}{2}]$  gives 0.73908513321516.

Solving the equation  $\cos(x) = x$  in  $[\frac{\pi}{2}; \pi]$  gives  $\emptyset$ .

Solving the equation  $x^3 - 2x^2 + \frac{1}{2} = 0$  in  $[-1; 2]$  gives:  $\{-0.45160596295578, 0.59696828323732, 1.8546376797185\}$ .

**Example 2:** We want to plot the curve of the function  $f$  defined by the condition:

$$\forall x \in \mathbf{R}, \int_x^{f(x)} \exp(t^2) dt = 1.$$

We have two possible methods:

1. We consider the function  $G: (x, y) \mapsto \int_x^y \exp(t^2) dt - 1$ , and we draw the implicit curve with equation  $G(x, y) = 0$ .
2. We determine a real number  $y_0$  such that  $\int_0^{y_0} \exp(t^2) dt = 1$  and we draw the solution to the differential equation  $y' = e^{x^2 - y^2}$  satisfying the initial condition  $y(0) = y_0$ .

Let's draw both:

```

1 \begin{luadraw}{name=int_solve}
2 local g = graph:new{window={-3,3,-3,3},size={10,10}}
3 local h = function(t) return math.exp(t^2) end
4 local G = function(x,y) return int(h,x,y)-1 end
5 local H = function(y) return G(0,y) end
6 local F = function(x,y) return math.exp(x^2-y^2) end
7 local y0 = solve(H,0,1)[1] -- solution de H(x)=0
8 g:Daxes({0,1,1}, {arrows="->"})
9 g:Dimplicit(G, {draw_options="line width=4.8pt,Pink"})
10 g:Dodesolve(F,0,y0,{draw_options="line width=0.8pt"})
11 g:Lineoptions("dashed","gray",4); g:DlineEq(1,-1,0); g:DlineEq(1,1,0) -- bissectrices
12 g:Dlabel("$\{\mathcal{C}_f\}$",Z(2.15,2),{pos="S"})
13 g:Show()
14 \end{luadraw}

```

Figure 26: Function  $f$  defined by  $\int_x^{f(x)} \exp(t^2) dt = 1$ .

We see that the two curves overlap well, however the first method (implicit curve) is much more computationally intensive, so method 2 is preferable.

## V Transformations

In the following:

- the argument  $L$  is either a complex number, a list of complex numbers, or a list of lists of complex numbers,
- the line  $d$  is a list of two complex numbers: a point on the line and a direction vector.

### 1) **affin**

The function **affin**( $L, d, v, k$ ) returns the image of  $L$  by the affinity of base line  $d$ , parallel to the vector  $v$  and of ratio  $k$ .

## 2) **ftransform**

The function **ftransform(L,f)** returns the image of  $L$  by the function  $f$ , which must be a function of the complex variable. If one of the elements of  $L$  is the complex number *cpx.Jump*, then it is returned as is in the result.

## 3) **hom**

The function **hom(L,factor,center)** returns the image of  $L$  by the homothety with center *center* and ratio *factor*. By default, the argument *center* is 0.

## 4) **inv**

The function **inv(L,radius,center)** returns the image of  $L$  by the inversion with respect to the circle with center *center* and radius *radius*. By default, the argument *center* is 0.

## 5) **proj**

The function **proj(L,d)** returns the image of  $L$  by the orthogonal projection onto the line  $d$ .

## 6) **projO**

The function **projO(L,d,v)** returns the image of  $L$  by projection onto the line  $d$  parallel to the vector  $v$ .

## 7) **rotate**

The function **rotate(L,angle,center)** returns the image of  $L$  by rotation with center *center* and angle *angle* (in degrees). By default, the argument *center* is 0.

## 8) **shift**

The function **shift(L,u)** returns the image of  $L$  by translation of vector  $u$ .

## 9) **simil**

The function **simil(L,factor,angle,center)** returns the image of  $L$  by the similarity of center *center*, ratio *factor*, and angle *angle* (in degrees). By default, the argument *center* is 0.

## 10) **sym**

The function **sym(L,d)** returns the image of  $L$  by the orthogonal symmetry of axis  $d$ .

## 11) **symG**

The function **symG(L,d,v)** returns the image of  $L$  by the symmetry about the line  $d$  followed by the translation of vector  $v$  (sliding symmetry).

## 12) **symO**

The function **symO(L,d)** returns the image of  $L$  by symmetry with respect to the line  $d$  and parallel to the vector  $v$  (oblique symmetry).

```

1 \begin{luadraw}{name=Sierpinski}
2 local g = graph:new{window={-5,5,-5,5},size={10,10}}
3 local i = cpx.I
4 local rand = math.random
5 local A, B, C = 5*i, -5-5*i, 5-5*i -- triangle initial
6 local T, niv = {{A,B,C}}, 5
7 for k = 1, niv do

```

```

8   T = concat( hom(T,0.5,A), hom(T,0.5,B), hom(T,0.5,C) )
9   end
10  for _,cp in ipairs(T) do
11      g:Filloptions("full", rgb(rand(),rand(),rand()))
12      g:Dpolyline(cp,true)
13  end
14  g:Show()
15  \end{luadraw}

```

Figure 27: Using Transformations

## VI Matrix Calculus

If  $f$  is an affine application of the complex plane, we will call the list (table) of  $f$  the matrix:

```
1 { f(0), Lf(1), Lf(i) }
```

where  $Lf$  denotes the linear part of  $f$  (we have  $Lf(1) = f(1) - f(0)$  and  $Lf(i) = f(i) - f(0)$ ). The identity matrix is denoted  $ID$  in the *luadraw* package; it simply corresponds to the list  $\{0, 1, i\}$ .

### 1) Matrix Calculations

#### **applymatrix** and **applyLmatrix**

- The function **applymatrix(z,M)** applies the matrix  $M$  to the complex  $z$  and returns the result (which is equivalent to calculating  $f(z)$  if  $M$  is the matrix of  $f$ ). When  $z$  is the complex *cpx.Jump* then the result is *cpx.Jump*. When  $z$  is a string then the function returns  $z$ .
- The function **applyLmatrix(z,M)** applies the linear part of the matrix  $M$  to the complex  $z$  and returns the result (which is equivalent to calculating  $Lf(z)$  if  $M$  is the matrix of  $f$ ). When  $z$  is the complex *cpx.Jump* then the result is *cpx.Jump*.

#### **composematrix**

The function **composematrix(M1,M2)** performs the matrix product  $M1 \times M2$  and returns the result.

#### **invmatrix**

The function **invmatrix(M)** calculates and returns the inverse of the matrix  $M$  when possible.

**matrixof**

- The function **matrixof(f)** calculates and returns the matrix of  $f$  (which must be an affine application of the complex plane).
- Example: `matrixof( function(z) return proj(z,{0,Z(1,-1)}) end )` returns  $\{0, Z(0.5, -0.5), Z(-0.5, 0.5)\}$  (matrix of the orthogonal projection onto the second bisector).

**mtransform and mLtransform**

- The function **mtransform(L,M)** applies the matrix  $M$  to the list  $L$  and returns the result.  $L$  must be a list of complex numbers or a list of lists of complex numbers. If one of them is the complex *cpx.Jump* or a string, then it is unchanged (and therefore returned as is).
- The function **mLtransform(L,M)** applies the linear part of the matrix  $M$  to the list  $L$  and returns the result.  $L$  must be a list of complex numbers. If one of them is the complex *cpx.Jump*, then it is unchanged.

**2) Matrix associated with the graph**

When creating a graph in the *luadraw* environment, for example:

```
1 local g = graph:new{window={-5,5,-5,5},size={10,10}}
```

The created  $g$  object has a transformation matrix that is initially the identity. All graphics methods used automatically apply the graph's transformation matrix. This matrix is designated `g.matrix`, but to manipulate it, the following methods are available.

**g:Composematrix()**

The **g:Composematrix(M)** method multiplies the graph matrix  $g$  by the matrix  $M$  (with  $M$  on the right) and assigns the result to the graph matrix. The argument  $M$  must therefore be a matrix.

**g:Det2d()**

The **g:Det2d()** method returns 1 when the transformation matrix has a positive determinant, and  $-1$  otherwise. This information is useful when we need to know whether the plane orientation has been changed or not.

**g:IDmatrix()**

The **g:IDmatrix()** method reassigns the identity to the graph matrix  $g$ .

**g:Mtransform()**

The **g:Mtransform(L)** method applies the graph matrix  $g$  to  $L$  and returns the result. The argument  $L$  must be a list of complex numbers, or a list of lists of complex numbers.

**g:MLtransform()**

The **g:MLtransform(L)** method applies the linear part of the graph matrix  $g$  to  $L$  and returns the result. The argument  $L$  must be a list of complex numbers, or a list of lists of complex numbers.

```
1 \begin{luadraw}{name=Pythagore}
2 local g = graph:new{window={-15,15,0,22},size={10,10}}
3 local a, b, c = 3, 4, 5 -- un triplet de Pythagore
4 local i, arccos, exp = cpx.I, math.acos, cpx.exp
5 local f1 = function(z)
6     return (z-c)*a/c*exp(-i*arccos(a/c))+c+i*c end
7 local M1 = matrixof(f1)
8 local f2 = function(z)
9     return z*b/c*exp(i*arccos(b/c))+i*c end
```

```

10 local M2 = matrixof(f2)
11 local arbre
12 arbre = function(n)
13     local color = mixcolor(ForestGreen,1,Brown,n)
14     g:Linecolor(color); g:Dsquare(0,c,1,"fill="..color)
15     if n > 0 then
16         g:Savematrix(); g:Composematrix(M1); arbre(n-1)
17         g:Restorematrix(); g:Savematrix(); g:Composematrix(M2)
18         arbre(n-1); g:Restorematrix()
19     end
20 end
21 arbre(8)
22 g:Show()
23 \end{luadraw}

```

Figure 28: Using the Graph Matrix

**g:Rotate()**

The **g:Rotate(*angle*, *center*)** method modifies the transformation matrix of the graph *g* by composing it with the rotation matrix with angle *angle* (in degrees) and center *center*. The argument *center* is a complex matrix that defaults to 0.

**g:Scale()**

The **g:Scale(*factor*, *center*)** method modifies the transformation matrix of the graph *g* by composing it with the homothety matrix with ratio *factor* and center *center*. The argument *center* is a complex matrix that defaults to 0.

**g:Savematrix() and g:Restorematrix()**

- The **g:Savematrix()** method saves the transformation matrix of graph *g* to a stack.
- The **g:Restorematrix()** method restores the transformation matrix of graph *g* to its last saved value.

**g:Setmatrix()**

The **g:Setmatrix(*M*)** method assigns matrix *M* to the transformation matrix of graph *g*.

**g:Shift()**

The **g:Shift(*v*)** method modifies the transformation matrix of graph *g* by composing it with the translation matrix of vector *v*, which must be a complex matrix.

```

1 \begin{luadraw}{name=free_art}
2 local du = math.sqrt(2)/2
3 local g = graph:new{window={1-du,4+du,1-du,4+du},
4 margin={0,0,0,0},size={7,7}}
5 local i = cpx.I
6 g:Linestyle("noline")
7 g:Filloptions("full","Navy",0.1)
8 for X = 1, 4 do
9   for Y = 1, 4 do
10    g:Savematrix()
11    g:Shift(X+i*Y); g:Rotate(45)
12    for k = 1, 25 do
13      g:Dsquare((1-i)/2,(1+i)/2,1)
14      g:Rotate(7); g:Scale(0.9)
15    end
16    g:Restorematrix()
17   end
18 end
19 g:Show()
20 \end{luadraw}

```

Figure 29: Using Shift, Rotate and Scale

### 3) View change. Change of coordinate system

**View change:** when creating a new graph, for example:

```
1 local g = graph:new{window={-5,5,-5,5},size={10,10}}
```

The option `window={xmin,xmax,ymin,ymax}` sets the view for graph `g`. This will be the  $[xmin, xmax] \times [ymin, ymax]$  block of  $\mathbf{R}^2$ , and all plots will be clipped by this window (except labels, which can overflow into the margins, but not beyond). Within this box, it is possible to define another box to create a new view, using the `g:Viewport(x1,x2,y1,y2)` method. The values of `x1`, `x2`, `y1`, `y2` refer to the initial window defined by the `window` option. From then on, everything outside this new area will be clipped, and the graph matrix will be reset to the same value. Therefore, you must first save the current graphics settings:

```
1 g:Saveattr()
2 g:Viewport(x1,x2,y1,y2)
```

To return to the previous view with the previous matrix, simply restore the graphics settings with the `g:Restoreattr()` method.

**Warning:** Each `Saveattr()` instruction must correspond to a `Restoreattr()` instruction, otherwise a compilation error will occur.

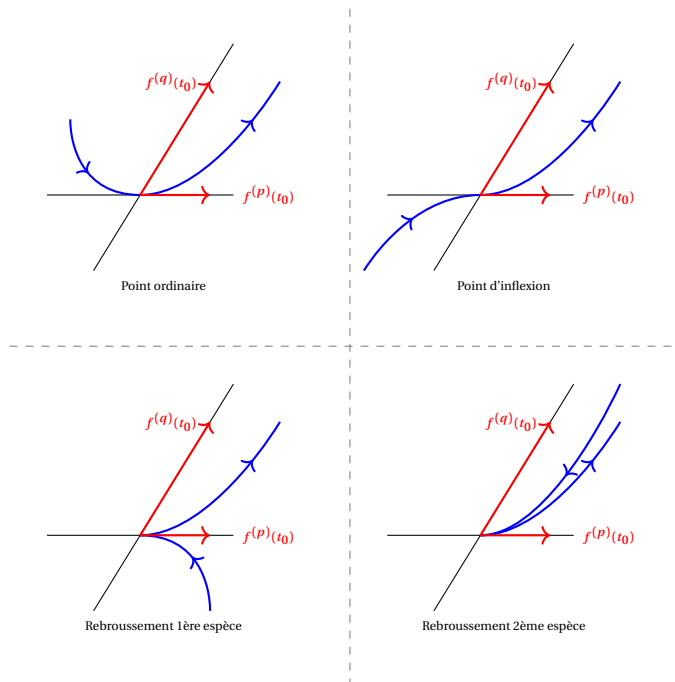

**Changing the coordinate system:** The coordinate system of the current view can be changed with the `g:Coordsystem(x1,x2,y1,y2,ortho)` method. This method will modify the graph matrix so that everything occurs as if the current view corresponded to the  $[x1,x2] \times [y1,y2]$  box. The optional Boolean argument *ortho* indicates whether the new coordinate system should be orthonormal or not (false by default). Since the graph matrix is modified, it is best to save the graphical parameters first and restore them later. This can be used, for example, to create multiple figures in the current graph.

```

1 \begin{luadraw}{name=viewport_changewin}
2 local g = graph:new{window={-5,5,-5,5},size={10,10}}
3 local i = cpx.I
4 g:Labelsize("tiny")
5 g:Writeln("\tikzset{->/.style={decoration={markings, mark=at position #1 with {\arrow{>}}},
6   ~ postaction={decorate}}}")
7 g:Dline({0,1},"dashed,gray"); g:Dline({0,i},"dashed,gray")
8 local legende = {"Point ordinaire", "Point d'inflexion", "Rebroussement 1ère espèce", "Rebroussement 2ème espèce"}
9 local A, B, C =(1+i)*0.75, 0.75, 0
10 local A2, B2 ={-1.25+i*0.5,-0.75-i*0.5,1.25-0.5*i, 0.5+i}, {-0.75,-0.75,0.75,0.75}
11 local u = {Z(-5,0),Z(0,0),-5-5*i,-5*i}
12 for k = 1, 4 do
13   g:Saveattr(); g:Viewport(u[k].re,u[k].re+5,u[k].im,u[k].im+5)
14   g:Coordsystem(-1.4,2.25,-1,1.25)
15   g:Composematrix({0,1,1+i}) -- pour pencher l'axe Oy
16   g:Dpolyline({{-1,1},{-i*0.5,i}}) -- axes
17   g:Lineoptions(nil,"blue",8)
18   g:Dpath({A2[k],(B2[k]+2*A2[k])/3,(C+5*B2[k])/6, C,"b"},"->=0.5")
19   g:Dpath({C,(C+5*B)/6,(B+2*A)/3,A,"b"},"->=0.75")
20   g:Dpolyline({{0,0.75},{0,0.75*i}},false,"->,red")
21   g:Dlabel(
22     legende[k],0.75-0.5*i, {pos="S"},
23     "$f^{(p)}(t_0)$",1,{pos="E",node_options="red"},
24     "$f^{(q)}(t_0)$",0.75*i,{pos="W",dist=0.05})
25   g:Restoreattr()
26 end
27 g:Show()
28 \end{luadraw}

```

Figure 30: Classification of the points of a parametric curve

## VII Adding Your Own Methods

Without having to modify the Lua source files associated with the *luadraw* package, you can add your own methods to the *graph* class, or modify an existing method. This is only useful if these modifications will be used in different graphs and/or different documents (otherwise, you can simply write a function locally in the graph where it's needed).

### 1) An Example

In the graph on page 13, we drew a vector field. To do this, we wrote a function that calculates the vectors before drawing, but this function is local. We could make it a global function (by removing the *local* keyword), which would then be usable throughout the document, but not in another document!

To generalize this function, we will need to create a Lua file that can then be imported into documents if necessary. To make the example a bit more consistent, we'll create a file that defines a function that calculates the vectors of a field, and that will add two new methods to the *graph* class: one to draw a vector field of a function  $f: (x, y) \rightarrow (x, y) \in \mathbf{R}^2$ , we'll name it *graph:Dvectorfield*, and another to draw a gradient field of a function  $f: (x, y) \rightarrow \mathbf{R}$ , we'll name it *graph:Dgradientfield*. Therefore, we'll call this file: *luadraw\_fields.lua*.

#### File contents:

```

1  -- luadraw_fields.lua
2  -- added methods to the graph class of the luadraw package
3  -- to draw vector or gradient fields
4  function field(f,x1,x2,y1,y2,grid,long) -- mathematical function, independent of the graph
5  -- calcule un champ de vecteurs dans le pavé [x1,x2]x[y1,y2]
6  -- f fonction de deux variables à valeurs dans R^2
7  -- grid = {nbx, nby} : nombre de vecteurs suivant x et suivant y
8  -- long = longueur d'un vecteur
9      if grid == nil then grid = {25,25} end
10     local deltax, deltay = (x2-x1)/(grid[1]-1), (y2-y1)/(grid[2]-1) -- x and y step
11     if long == nil then long = math.min(deltax,deltay) end -- default length
12     local vectors = {} -- will contain the list of vectors
13     local x, y, v = x1
14     for _ = 1, grid[1] do -- a loop on x
15         y = y1
16         for _ = 1, grid[2] do -- a loop on y
17             v = f(x,y) -- we assume that v is well defined
18             v = Z(v[1],v[2]) -- to complex number
19             if not cpx.isNul(v) then
20                 v = v/cpx.abs(v)*long -- normalization
21                 table.insert(vectors, {Z(x,y), Z(x,y)+v}) -- we add the vector
22             end
23             y = y+deltay
24         end
25         x = x+deltax
26     end
27     return vectors -- we return the result (polygonal line)
28 end
29
30 function graph:Dvectorfield(f,args) -- added a method to the graph class
31 -- draws a vector field
32 -- f is a function of two variables with values in R^2
33 -- args is a 4-field table:
34 -- { view={x1,x2,y1,y2}, grid={nbx,nby}, long=, draw_options="" }
35     args = args or {}
36     local view = args.view or {self:Xinf(),self:Xsup(),self:Yinf(),self:Ysup()} -- default user reference
37     local vectors = field(f,view[1],view[2],view[3],view[4],args.grid,args.long) -- field calculation
38     self:Dpolyline(vectors,false,args.draw_options) -- the drawing (non-closed polygonal line)
39 end
40
41 function graph:Dgradientfield(f,args) -- added another method to the graph class
42 -- draws a gradient field
43 -- f is a function of two variables with values in R

```

```

44 -- args is a 4-field table:
45 -- { view={x1,x2,y1,y2}, grid={nbx,nby}, long=, draw_options="" }
46 local h = 1e-6
47 local grad_f = function(x,y) -- gradient function of f
48     return { (f(x+h,y)-f(x-h,y))/(2*h), (f(x,y+h)-f(x,y-h))/(2*h) }
49 end
50 self:Dvectorfield(grad_f,args) -- we use the previous method
51 end

```

## 2) How to import the file

There are two methods for this:

1. With the Lua instruction *dofile*. This can be written, for example, in the preamble after the package declaration:

```

\usepackage[] {luadraw}
\directlua{dofile("<path>/luadraw_fields.lua")}

```

Of course, you will need to replace `<path>` with the path to this file.

The instruction `\directlua{dofile("<path>/luadraw_fields.lua")}` can be placed elsewhere in the document, as long as it is after the package has been loaded (otherwise the *graph* class will not be recognized when reading the file). We can also place the instruction `dofile("<path>/luadraw_fields.lua")` in a *luacode* environment, and therefore in particular in a *luadraw* environment.

As soon as the file is imported, the new methods are available for the rest of the document.

This approach has at least two drawbacks: it must be remembered each time `<path>` is used, and secondly, the *dofile* instruction does not check whether the file has already been read. For these reasons, we prefer the following method.

2. With the Lua instruction *require*. For example, we can write it in the preamble after the package declaration:

```

\usepackage[] {luadraw}
\directlua{require "luadraw_fields"}

```

Note the absence of the path (and the lua extension is unnecessary).

The `\directlua{require "luadraw_fields"}` instruction can be placed elsewhere in the document, provided it is after the package has been loaded (otherwise the *graph* class will not be recognized when reading the file). We can also place the `require "luadraw_fields"` instruction in a *luacode* environment, and therefore in particular in a *luadraw* environment.

The *require* instruction checks whether the file has already been loaded or not, which is preferable. However, Lua must be able to find this file, and the easiest way to do this is for it to be somewhere in a tree structure known to TeX. For example, you can create the following path in your local *texmf*:

```
texmf/tex/lualatex/myluafiles/
```

then copy the file *luadraw\_fields.lua* into the *myluafiles* folder.

```

1 \begin{luadraw}{name=fields}
2 require "luadraw_fields" -- import des nouvelles méthodes
3 local g = graph:new{window={0,21,0,10},size={16,10}}
4 local i = cpx.I
5 g:Labelsize("footnotesize")
6 local f = function(x,y) return {x-x*y,-y+x*y} end -- Volterra
7 local F = function(x,y) return x^2+y^2+x*y-6 end
8 local H = function(t,Y) return f(Y[1],Y[2]) end
9 -- graphique du haut
10 g:Saveattr();g:Viewport(0,10,0,10);g:Coordsystem(-5,5,-5,5)
11 g:Dgradbox({-4.5-4.5*i,4.5+4.5*i,1,1}, {originloc=0,originnum={0,0},grid=true,title="gradient field,
    ~ $f(x,y)=x^2+y^2+xy-6$"})
12 g:Arrows("->"); g:Lineoptions(nil,"blue",6)
13 g:Dgradientfield(F,{view={-4,4,-4,4},grid={15,15},long=0.5})
14 g:Arrows("-"); g:Lineoptions(nil,"Crimson",12); g:Dimplicit(F, {view={-4,4,-4,4}})
15 g:Restoreattr()

```

```

16 -- graphique du bas
17 g:Saveattr();g:Viewport(11,21,0,10);g:Coordsystem(-5,5,-5,5)
18 g:Dgradbox({-4.5-4.5*i,4.5+4.5*i,1,1}, {originloc=0,originnum={0,0},grid=true,title="vector field,
  ↳ $f(x,y)=(x-xy,-y+xy)$"}))
19 g:Arrows(">"); g:Lineoptions(nil,"blue",6); g:Dvectorfield(f,{view={-4,4,-4,4}})
20 g:Arrows("-");g:Lineoptions(nil,"Crimson",12)
21 g:Dodesolve(H,0,{2,3},{t={0,50},out={2,3},nbdots=250})
22 g:Restoreattr()
23 g:Show()
24 \end{luadraw}

```

Figure 31: Using the new methods

### 3) Modifying an existing method

Let's take for example the method `DplotXY(X,Y,draw_options)`, which takes two lists (tables) of real numbers as arguments and draws the polygonal line formed by the points with coordinates  $(X[k], Y[k])$ . We'll modify it to account for the case where  $X$  is a list of names (strings). In this case, the names will be displayed below the x-axis (with x-axis  $k$  for the  $k$ th name) and the polygonal line formed by the points with coordinates  $(k, Y[k])$  will be drawn. Otherwise, we'll use the same method as the old method. To do this, simply rewrite the method (in a Lua file so that it can be imported later):

```

1 function graph:DplotXY(X,Y,draw_options)
2 -- X is a list of real numbers or strings
3 -- Y is a list of real numbers of the same length as X    local L = {} -- liste des points à dessiner
4 if type(X[1]) == "number" then -- list of real numbers
5   for k,x in ipairs(X) do
6     table.insert(L,Z(x,Y[k]))
7   end
8 else
9   local noms = {} -- list of labels to place
10  for k = 1, #X do
11    table.insert(L,Z(k,Y[k]))
12    insert(noms,{X[k],k,{pos="E",node_options="rotate=-90"}})
13  end
14  self:Dlabel(table.unpack(noms)) -- drawing labels
15 end
16 self:Dpolyline(L,draw_options) -- drawing the curve
17 end

```

As soon as the file is imported, this new definition will overwrite the old one (for the rest of the document). Of course, you could imagine adding other options to the drawing style, for example (lines, bars, dots, etc.).

```

1 \begin{luadraw}{name=newDplotXY}
2 require "luadraw_fields" -- import of the modified method

```

```

3 local g = graph:new{window={-0.5,11,-1,20}, margin={0.5,0.5,0.5,1}, size={10,10,0}}
4 g:Labelsize("scriptsize")
5 local X, Y = {}, {} -- we define two lists X and Y, we could also read them in a file
6 for k = 1, 10 do
7     table.insert(X,"nom"..k)
8     table.insert(Y,math.random(1,20))
9 end
10 defaultlabelshift = 0
11 g:Daxes({0,1,2},{limits={{0,10},{0,20}}, labelpos={"none","left"},arrows="->", grid=true})
12 g:DplotXY(X,Y,"line width=0.8pt, blue")
13 g:Show()
14 \end{luadraw}

```

Figure 32: Modifying an existing method

# 3D Drawing

Figure 1: Col point at  $M(0,0,0)$  ( $z = x^2 - y^2$ )

## I Introduction

### 1) Prerequisites

- This document presents the use of the *luadraw* package with the *3d* global option: `\usepackage[3d]{luadraw}`.
- The package loads the *luadraw\_graph2d.lua* module, which defines the *graph* class and provides the *luadraw* environment for creating graphs in Lua. Everything said in the previous chapter (Drawing 2d) therefore applies, and is assumed to be known here.
- The *3d* global option also allows the loading of the *luadraw\_graph3d.lua* module. This also defines the *graph3d* class (which relies on the *graph* class) for 3D drawings.

### 2) Some reminders

- Another global package option: *noexec*. When this global option is mentioned, the default value of the *exec* option for the *luadraw* environment will be false (and no longer true).
- When a graph is finished, it is exported in tikz format, so this package also loads the tikz package and the libraries:

- *patterns*
  - *plotmarks*
  - *arrows.meta*
  - *decorations.markings*
- Graphs are created in a *luadraw* environment, which calls *luacode*, so the *textbf* Lua language must be used in this environment.
  - Saving the *tkz* file: the chart is exported in *tkz* format to a file (with the *tkz* extension). By default, it is saved in the *\_luadraw* folder, which is a subfolder of the current folder (containing the master document), but it is possible to specify a path to another subfolder. with the global option *cachedir=*.
  - The environment options are:
    - *name = ...*: allows you to name the resulting *tkz* file. It is given a name without an extension (the extension will be automatically added; it is *.tkz*). If this option is omitted, then a default name is used, which is the name of the master file followed by a number.
    - *exec = true/false*: Allows you to execute or not the Lua code included in the environment. By default, this option is true, **EXCEPT** if the global option *noexec* was mentioned in the preamble with the package declaration. When a complex graph that requires a lot of calculations is developed, it may be useful to add the option *exec=false*; this will avoid recalculating the same graph for future compilations.
    - *auto = true/false*: Allows you to automatically include or not the *tkz* file in place of the *luadraw* environment when the *exec* option is false. By default, the *auto* option is true.

### 3) Creating a 3D Graph

```
\begin{luadraw}{ name=<filename>, exec=true/false, auto=true/false }
-- create a new graph and give it a local name
local g = graph3d:new{ window3d={x1,x2,y1,y2,z1,z2}, adjust2d=true/false, viewdir={30,60},
  ↳ window={x1,x2,y1,y2,xscale,yscale}, margin={top,right,bottom,left}, size={width,height,ratio}, bg="color",
  ↳ border=true/false }
-- build graph g
graph instructions in Lua language ...
-- display graph g and save it in the file <filename>.tkz
g:Show()
-- or Save only in the <filename>.tkz file
g:Save()
\end{luadraw}
```

Creation is done in a *luadraw* environment. This creation is done on the first line inside the environment by naming the graph:

```
1 local g = graph3d:new{ window3d={x1,x2,y1,y2,z1,z2}, adjust2d=true/false, viewdir={30,60},
  ↳ window={x1,x2,y1,y2,xscale,yscale}, margin={left,right,top,bottom}, size={width,height,ratio}, bg="color",
  ↳ border=true/false }
```

The *graph3d* class is defined in the *luadraw* package using the global option *3d*. This class is instantiated by invoking its constructor and giving it a name (here it's *g*). This is done locally so that the graph *g* thus created will no longer exist once it leaves the environment (otherwise *g* would remain in memory until the end of the document).

- The (optional) parameter *window3d* defines the  $\mathbf{R}^3$  block corresponding to the graph: it is  $[x_1, x_2] \times [y_1, y_2] \times [z_1, z_2]$ . By default, it is  $[-5, 5] \times [-5, 5] \times [-5, 5]$ .
- The (optional) *adjust2d* parameter indicates whether the 2D window that will contain the orthographic projection of the 3D drawing should be determined automatically (false by default). This 2D window corresponds to the *window* argument.

- The (optional) parameter *viewdir* is a table that defines the two viewing angles (in degrees) used for the orthographic projection, which is the default projection (*viewdir*= $\{30,60\}$  by default). The following figure shows what these two angles correspond to.

Figure 2: Viewing Angles

- The other parameters are those of the *graph* class, described in Chapter 1.

#### Graph construction.

- The instantiated object (*g* in the example) has all the methods of the *graph* class, plus methods specific to 3D.
- The *graph3d* class also provides a number of mathematical functions specific to 3D.

#### 4) Affine Projection Modes

By default, *luadraw* uses orthographic projection (orthogonal projection on the screen). This is defined by two angles given to the *viewdir* option during creation, or to the *g:Setviewdir()* method.

There are three other possible affine projection modes, but they are not orthogonal projections:

- three cavalier perspectives: on the *yz* plane, or on the *xz* plane, or on the *xy* plane. These are defined using two parameters: a positive number *k* and an angle in degrees *alpha*, which are explained in the following figure.
- an isometric perspective.

Figure 3: Affine Projection Modes

These projection modes are accessed via the function **perspective(mode,k,alpha)**, where the argument *mode* can be "yz", "xz", or "xy" (for the three cavalier perspectives) or "iso" for the isometric perspective. If *mode* has an unrecognized value, then the orthographic projection is selected. For the first three modes, the values of the parameters *k* (0.5 by default) and *alpha* (45 by default) are also provided; these values are unnecessary for the fourth mode.

This function is used either with the *viewdir* option when creating the graphic object, for example:

```
1 local g = graph3d:new{ viewdir = perspective("yz",0.65,60) }
```

or during graph creation with the *g:Setviewdir()* method:

```
1 g:Setviewdir(perspective("yz",0.65,60))
```

## 5) Central Projection

Since version 2.4, *luadraw* also offers central projection. Unlike previous modes, **this projection is not affine**, and furthermore, it is not defined for all points in space, which can lead to errors, thus requiring thought and adjustments. This projection is defined by:

- A camera, which is a point in space stored in a variable called *camera* and which should not be modified directly.
- A target, which is a point in space stored in a variable called *target* and which should not be modified directly.

## II

The plane passing through the *target* and orthogonal to the *target* - *camera* axis is the projection plane; it represents the screen. As with the previous modes, the central projection is accessed via the *perspective* function:

**perspective("central",camera,target),**

or

**perspective("central",theta,phi,d,target),**

In the first case, the values of *camera* and *target* are given (3D points; by default, *target* is the origin). In the second case, the three arguments *theta*, *phi*, and *d* are used to position the camera according to the following diagram:

Figure 4: Central projection

The default values are:  $\theta=30$  (degrees),  $\phi=60$ ,  $d=15$ ,  $\text{target}=\text{Origin}$ . This function is used either with the *viewdir* option when creating the graph object, for example:

```
1 local g = graph3d:new{ viewdir = perspective("central",40,60) }
```

or during graph creation with the *g:Setviewdir()* method:

```
1 g:Setviewdir(perspective("central",40,60))
```

### III The pt3d Class

#### 1) Representation of Points and Vectors

- The usual space is  $\mathbf{R}^3$ , so points and vectors are triplets of real numbers (called 3d points). Four triplets have specific names (predefined variables), namely:
  - **Origin**, which represents the triplet (0,0,0).
  - **vecI**, which represents the triplet (1,0,0).
  - **vecJ**, which represents the triplet (0,1,0).
  - **vecK**, which represents the triplet (0,0,1).

Added to this is the variable **ID3d**, which is the table  $\{\text{Origin}, \text{vecI}, \text{vecJ}, \text{vecK}\}$  representing the 3D unit matrix. By default, it is the transformation matrix of the 3D graph.

- The class *pt3d* (which is automatically loaded) defines the real triplets, the possible operations, and a number of methods. To create a 3D point, there are three methods:
  - Cartesian definition: the function **M(x,y,z)** returns the triplet (x,y,z). This triplet can also be obtained by doing:  $x*\text{vecI}+y*\text{vecJ}+z*\text{vecK}$ .
  - Cylindrical definition: the function **Mc(r,θ,z)** (angle expressed in radians) returns the triplet  $(r \cos(\theta), r \sin(\theta), z)$ .
  - Spherical definition: the function **Ms(r,θ,φ)** returns the triplet  $(r \cos(\theta) \sin(\phi), r \sin(\theta) \sin(\phi), r \cos(\phi))$  (angles expressed in radians).

Accessing the components of a 3D point: if a variable *A* denotes a 3D point, then its three components are *A.x*, *A.y*, and *A.z*.

To test whether a variable *A* designates a 3D point, we use the **isPoint3d()** function, which returns a Boolean.

Conversion: To convert a real or complex number into a 3D point, we use the **toPoint3d()** function.

## 2) Operations on 3D Points

These operations are the usual operations with the usual symbols:

- Addition (+), difference (-), and negative (-).
- The product by a scalar, if  $k$  is a real number,  $k*M(x,y,z)$  returns  $M(kx,ky,kz)$ .
- A 3D point can be divided by a scalar; for example, if  $A$  and  $B$  are two 3D points, then the midpoint is simply written  $(A + B)/2$ .
- The equality of two 3D points can be tested with the symbol  $=$ .

## 3) Methods of the class *pt3d*

These are:

- **pt3d.abs(u)**: Returns the Euclidean norm of the 3d point  $u$ .
- **pt3d.abs2(u)**: Returns the squared Euclidean norm of the 3d point  $u$ .
- **pt3d.N1(u)**: Returns the 1-norm of the 3d point  $u$ . If  $u = M(x, y, z)$ , then *pt3d.N1(u)* returns  $|x| + |y| + |z|$ .
- **pt3d.dot(u,v)**: Returns the dot product between the vectors (3d points)  $u$  and  $v$ .
- **pt3d.det(u,v,w)**: Returns the determinant between the vectors (3D points)  $u$ ,  $v$ , and  $w$ .
- **pt3d.prod(u,v)**: Returns the cross product between the vectors (3D points)  $u$  and  $v$ .
- **pt3d.angle3d(u,v,epsilon)**: Returns the angular difference (in radians) between the vectors (3D points)  $u$  and  $v$ , assumed to be non-zero. The (optional) argument *epsilon* is 0 by default; it indicates how close a given equality test is to a floating point.
- **pt3d.normalize(u)**: Returns the normalized vector (3D point)  $u$  (returns *nil* if  $u$  is zero).
- **pt3d.round(u,nbDeci)**: Returns a 3D point whose components are those of the 3D point  $u$  rounded to *nbDeci* decimal places.

## 4) Mathematical Functions

In the file defining the *pt3d* class, some mathematical functions are introduced:

- **isobar3d(L)**: Returns the isobarycenter of the 3D points in the list (table)  $L$  (elements of  $L$  that are not 3D points are ignored).
- **insert3d(L,A,epsilon)**: This function inserts the 3D point  $A$  into the list  $L$ , which must be a **variable** (and which will therefore be modified). Point  $A$  is inserted **without duplicates** and the function returns its position (index) in list  $L$  after insertion. The (optional) argument *epsilon* is 0 by default, indicating how closely the comparisons are made.
- **polyline2path3d(L)**: this function returns  $L$  which is a list of 3d points or a list of lists of 3d points, in the form of a path (which can be drawn with the *g:Dpath3d()* method).

## 5) Displaying a Variable in the Terminal

The instruction **whatis(variable,msg)** displays the type of the *variable* and its contents in the terminal during compilation. Recognized types include the predefined types plus: *complex number*, *list of (complex) numbers*, and *list of lists of (complex) numbers*, *3D point*, *list of 3D points*, *list of lists of 3D points*. The argument *msg* is an optional string (empty by default) which is displayed with the type to locate the variable in the terminal.

## IV Graphics Methods

All 2D graphics methods apply. Added to this is the ability to draw polygonal lines, segments, straight lines, curves, paths, points, labels, planes, and solids in space. With solids, we also have the concept of facets, which was not found in 2D.

3D graphics methods will automatically calculate the projection onto the screen plane. After applying the 3D transformation matrix associated with the graphic (which is the default identity) to the objects, the 2D graphics methods will then take over.

The method that applies the 3D matrix and performs the projection onto the screen (plane passing through the origin and normal to the unit vector directed towards the observer and defined by the viewing angles) is: **g:Proj3d(L)** where  $L$  is either a 3D point, a list of 3D points, or a list of lists of 3D points. This function returns complex numbers (affixes of the projected points onto the screen).

**Warning:** when the 3d matrix of the graph is not a linear transformation, the projection onto the screen of a vector  $u$  in space is not **g:Proj3d(u)**, but **g:Proj3d(A+u)-g:Proj3d(A)** where  $A$  denotes any point in space. To avoid these calculations, the method **g:Proj3dV()** has been introduced, it projects the **vectors** onto the screen, and returns complex numbers (affixes of the projected vectors onto the screen).

### 1) Line Drawing

#### Polygonal Line: Dpolyline3d

The method **g:Dpolyline3d(L,close,draw\_options,clip)** (where  $g$  denotes the graph being created),  $L$  is a 3D polygonal line (list of 3D point lists), *close* is an optional argument that is *true* or *false* indicating whether the line should be closed or not (*false* by default), and *draw\_options* is a string that will be passed directly to the `\draw` instruction in the export. The *clip* argument is set to *false* by default. It indicates whether the line  $L$  should be clipped to the current 3D window.

#### Right Angle: Dangle3d

The **g:Dangle3d(B,A,C,r,draw\_options,clip)** method draws the angle  $BAC$  with a parallelogram (only two sides are drawn). The optional argument  $r$  specifies the length of one side (0.25 by default). The parallelogram is in the plane defined by points  $A$ ,  $B$ , and  $C$ , so they should not be aligned. The *draw\_options* argument is a string (empty by default) that will be passed as is to the `\draw` instruction. The *clip* argument is set to *false* by default; it indicates whether the plot should be clipped to the current 3D window.

#### Segment: Dseg3d

The **g:Dseg3d(seg,scale,draw\_options,clip)** method draws the segment defined by the *seg* argument, which must be a list of two 3D points. The optional *scale* argument (1 by default) is a number that allows you to increase or decrease the length of the segment (the natural length is multiplied by *scale*). The *draw\_options* argument is a string (empty by default) that will be passed as is to the `\draw` instruction. The *clip* argument is set to *false* by default; it indicates whether the plot should be clipped to the current 3D window.

#### Line: Dline3d

The method **g:Dline3d(d,draw\_options,clip)** draws the line  $d$ , which is a list of type  $\{A,u\}$  where  $A$  represents a point on the line (3d point) and  $u$  a direction vector (a non-zero 3d point).

Variant: the method **g:Dline3d(A,B,draw\_options,clip)** draws the line passing through the points  $A$  and  $B$  (two 3d points). The argument *draw\_options* is a string (empty by default) that will be passed as is to the `\draw` instruction. The *clip* argument is set to *false* by default; it indicates whether the plot should be clipped to the current 3D window.

The **g:Line3d2seg(d,scale)** method returns a table consisting of two 3D points representing a segment. This segment is the portion of the line  $d$  inside the current 3D window. The *scale* argument (1 by default) allows you to vary the size of this segment. When the window is too small, the intersection may be empty.

#### Circular arc: Darc3d

- The method **g:Darc3d(B,A,C,r,sens,normal,draw\_options,clip)** draws a circular arc with center  $A$  (3d point), radius  $r$ , going from  $B$  (3d point) to  $C$  (3d point) in the forward direction if the argument *sens* is 1, and in the reverse direction

otherwise. This arc is drawn in the plane containing the three points  $A$ ,  $B$ , and  $C$ . When these three points are aligned, the argument *normal* (non-zero 3d point) must be specified, which represents a vector normal to the plane. This plane is oriented by the vector product  $\vec{AB} \wedge \vec{AC}$  or by the vector *normal* if it is specified. The *draw\_options* argument is a string (empty by default) that will be passed as is to the `\draw` instruction. The *clip* argument is set to *false* by default; it indicates whether the path should be clipped to the current 3D window.

- The `arc3d(B,A,C,r,sense,normal)` function returns the list of points of this arc (3D polygonal line).
- The `arc3db(B,A,C,r,sense,normal)` function returns this arc as a 3D path (see `Dpath3d`) using Bézier curves.

### Circle: `Dcircle3d`

- The method `g:Dcircle3d(I,R,normal,draw_options,clip)` draws the circle with center  $I$  (3D point) and radius  $R$ , in the plane containing  $I$  and normal to the vector defined by the argument *normal* (non-zero 3D point). The argument *draw\_options* is a string (empty by default) that will be passed as is to the instruction `\draw`. The argument *clip* is set to *false* by default; it indicates whether the plot should be clipped to the current 3D window. Another possible syntax: `g:Dcircle3d(C,draw_options,clip)` where  $C=\{I,R,normal\}$ .
- The `circle3d(I,R,normal)` function returns the list of points on this circle (3D polygonal line).
- The `circle3db(I,R,normal)` function returns this circle as a 3D path (see `Dpath3d`) using Bézier curves.

### 3D Path: `Dpath3d`

The `g:Dpath3d(path,draw_options,clip)` method draws the *path*. The *draw\_options* argument is a string that will be passed directly to the `\draw` instruction. The *clip* argument is set to *false* by default; it indicates whether the path should be clipped to the current 3D window. The argument *path* is a list of 3D points followed by instructions (strings) that work on the same principle as in 2D. The instructions are:

- `"m"` for moveto,
- `"l"` for lineto,
- `"b"` for Bezier (two control points are required),
- `"c"` for circle (one point on the circle, the center, and a normal vector are required),
- `"ca"` for arc (three points, a radius, a direction, and possibly a normal vector are required),
- `"cl"` for close (closes the current component).

Here, for example, is the code in figure 2.

```

1 \begin{luadraw}{name=viewdir}
2 local g = graph3d:new{ size={8,8} }
3 local i = cpx.I
4 local O, A = Origin, M(4,4,4)
5 local B, C, D, E = pxy(A), px(A), py(A), pz(A) --projeté de A sur le plan xOy et sur les axes
6 g:Dpolyline3d( {{O,A},{-5*vecI,5*vecI},{-5*vecJ,5*vecJ},{-5*vecK,5*vecK}}, "->" ) -- axes
7 g:Dpolyline3d( {{E,A,B,O}}, {C,B,D}}, "dashed")
8 g:Dpath3d( {C,O,B,2.5,1,"ca",0,"l", "cl"}, "draw=none,fill=cyan,fill opacity=0.8") --secteur angulaire
9 g:Darc3d(C,O,B,2.5,1,"->") -- arc de cercle pour theta
10 g:Dpath3d( {E,O,A,2.5,1,"ca",0,"l", "cl"}, "draw=none,fill=cyan,fill opacity=0.8") --secteur angulaire
11 g:Darc3d(E,O,A,2.5,1,"->") -- arc de cercle pour phi
12 g:Dballdots3d(O) -- le point origine sous forme d'une petite sphère
13 g:Labelsize("footnotesize")
14 g:Dlabel3d(
15     "$x$", 5.25*vecI,{}, "$y$", 5.25*vecJ,{}, "$z$", 5.25*vecK,{},
16     "vers observateur", A, {pos="E"},
17     "$0$", O, {pos="NW"},
18     "$\\theta$", (B+C)/2, {pos="N", dist=0.15},
19     "$\\varphi$", (A+E)/2, {pos="S",dist=0.25}
20 )

```

```

21 g:Dlabel("viewdir=\\{$\\theta,\\varphi$\\} (en degrés)",-5*i,{pos="N"}) -- label 2d
22 g:Show()
23 \\end{luadraw}

```

### Plane: Dplane

The method **g:Dplane(P,V,L1,L2,mode,draw\_options)** draws the edges of the plane  $P = \{A, u\}$  where  $A$  is a point in the plane and  $u$  is a normal vector to the plane ( $P$  is therefore a table of two 3D points). The argument  $V$  must be a non-zero vector in the plane  $P$ ,  $L_1$  and  $L_2$  are two lengths. The method constructs a parallelogram centered on  $A$ , with one side  $L_1 \frac{V}{\|V\|}$  and the other  $L_2 \frac{W}{\|W\|}$  where  $W = u \wedge V$ . The argument *mode* is a natural number indicating the edges to draw. To calculate this integer, we use the predefined variables: *top* (=8), *right* (=4), *bottom* (=2), *left* (=1), and *all* (=15), which can be added together, for example:

- mode = bottom+left: for the bottom and left sides
- mode = top+right+bottom: for the top, right, and bottom sides
- etc

By default, the mode is *all*, which corresponds to *top+right+bottom+left*.

```

1  \\begin{luadraw}{name=Dplane}
2  local g = graph3d:new{size={8,8},window={-5.25,3,-2.5,2.5},margin={0,0,0,0},border=true}
3  local i = cpx.I
4  g:Labelsize("footnotesize")
5  local A = Origin
6  local P = {A, vecK}
7  g:Dplane(P, vecJ, 6, 6, left+bottom)
8  g:Dcrossdots3d({A,vecK},nil,0.75)
9  g:Dseg3d({A,A+2*vecK},"->")
10 g:Dangle3d(-vecJ,A,vecK,0.25)
11 g:Dpolyline3d({{M(3.5,-3,0),M(3.5,3,0)},{M(3,-3.5,0), M(-3,-3.5,0)}}, "->,line width=0.8pt")
12 g:Dlabel3d("$A$",A,{pos="E"},
13   "$u$",2*vecK,{},
14   "$P$", M(3,-3,0),{pos="NE", dir={vecJ,-vecI}},
15   "$L_1\\frac{V}{\\|V\\|}$ (bottom)", M(3.5,0,0), {pos="S"},
16   "$L_2\\frac{W}{\\|W\\|}$ (left)", M(0,-3.5,0), {pos="N",dir={-vecI,-vecJ}}
17 )
18 g:Show()
19 \\end{luadraw}

```

Figure 5: Dplane, example with mode = left+bottom

**Warning** : The concepts of top, right, bottom, and left are relative! They depend on the direction of the vectors  $u$  (vector normal to the plane) and  $V$  (vector given in the plane). The third vector  $W$  is the cross product  $u \wedge V$ .

### Parametric curve: Dparametric3d

- The function **parametric3d(p,t1,t2,nbdots,discont,nbdiv)** calculates the points of the curve and returns a 3D polygonal line (no drawing).

- The argument  $p$  is the parameterization. It must be a function of a real variable  $t$  with values in  $\mathbf{R}^3$  (the images are 3D points), for example: `local p = function(t) return Mc(3,t,t/3) end`
  - The arguments  $t1$  and  $t2$  are mandatory with  $t1 < t2$ ; they form the bounds of the interval for the parameter.
  - The argument  $nbdots$  is optional; it is the (minimum) number of points to calculate; it is 40 by default.
  - The argument  $discont$  is an optional boolean that indicates whether there are discontinuities or not. It is *false* by default.
  - The argument  $nbddiv$  is a positive integer equal to 5 by default and indicates the number of times the interval between two consecutive parameter values can be split in two (dichotomized) when the corresponding points are too far apart.
- The method **g:Dparametric3d(p,args)** calculates the points and draws the curve parameterized by  $p$ . The *args* parameter is a 6-field table:

```
{ t={t1,t2}, nbdots=40, discont=true/false, clip=true/false, nbddiv=5, draw_options="" }
```

- By default, the  $t$  field is equal to  $\{g:Xinf(),g:Xsup()\}$ ,
- the  $nbdots$  field is equal to 40,
- the  $discont$  field is equal to *false*,
- the  $nbddiv$  field is equal to 5,
- the  $clip$  field is equal to *false*, it indicates whether the curve should be clipped with the current 3D window.
- the  $draw\_options$  field is an empty string (this will be passed as is to the *\draw* instruction).

```
1 \begin{luadraw}{name=Dparametric3d}
2 local g = graph3d:new{window3d={-4,4,-4,4,-3,3}, window={-7.5,6.5,-7,6}, size={8,8}}
3 local pi = math.pi
4 g:Labelsize("footnotesize")
5 local p = function(t) return Mc(3,t,t/3) end
6 local L = parametric3d(p,-2*pi,2*pi,25,false,2)
7 g:Dboxaxes3d({grid=true,gridcolor="gray",fillcolor="LightGray"})

```

Figure 6: A curve and its projections onto three planes

### Parameterization of a Polygonal Line: *curvilinear\_param3d*

Let  $L$  be a list of 3D points representing a continuous ""line. It is possible to obtain a parameterization of this line based on a parameter  $t$  between 0 and 1 ( $t$  is the curvilinear abscissa divided by the total length of  $L$ ).

The function **curvilinear\_param3d(L,close)** returns a function of one variable  $t \in [0; 1]$  and values on the line  $L$  (3D points). The value at  $t = 0$  is the first point of  $L$ , and the value at  $t = 1$  is the last point; This function is followed by a number representing the total length of  $L$ . The optional argument *close* indicates whether the line  $L$  should be closed (*false* by default).

### The reference: Dboxaxes3d

The **g:Dboxaxes3d( args )** method allows you to draw the three axes, with a number of options defined in the *args* table. These options are:

- **xaxe=true/false**, **yaxe=true/false**, and **zaxe=true/false**: Indicates whether the corresponding axes should be drawn or not (true by default).
- **drawbox=true/false**: Indicates whether a box should be drawn with the axes (false by default).
- **grid=true/false**: Indicates whether a grid should be drawn (one for  $x$ , one for  $y$ , and one for  $z$ ). When this option is true, the following options can also be used:
  - **gridwidth** (=1 by default) indicates the grid line thickness in tenths of a point.
  - **gridcolor** (black by default) indicates the grid color.
  - **fillcolor** ("" by default) allows you to paint the grid background or not.
- **xlimits={x1,x2}**, **ylimits={y1,y2}**, **zlimits={z1,z2}**: Allows you to define the three intervals used for the axis lengths. By default, these are the values provided to the **window3d** argument when creating the graph.
- **xgradlimits={x1,x2}**, **ygradlimits={y1,y2}**, **zgradlimits={z1,z2}**: Allows you to define the three graduation intervals on the axes. By default, these options are set to "auto," meaning they take the same values as **xlimits**, **ylimits**, and **zlimits**.
- **xyzstep**: Specifies the tick step on all three axes (1 by default).
- **xstep**, **ystep**, **zstep**: Specifies the tick step on each axis (value of **xyzstep** by default).
- **xyzticks** (0.2 by default): Specifies the length of the tick marks.
- **labels** (true by default): Specifies whether or not to display the tick mark values.

- `xlabelsep`, `ylabelsep`, `zlabelsep`: Specifies the distance between the labels and the graduations (0.25 by default).
- `xlabelstyle`, `ylabelstyle`, `zlabelstyle`: Specifies the label style, i.e., the position relative to the anchor point. By default, the current style is applied.
- `xlegend` ("x" by default), `ylegend` ("y" by default), `zlegend` ("z" by default): Allows you to define a legend for the axes.
- `xlegendsep`, `ylegendsep`, `zlegendsep`: Specifies the distance between the legends and the graduations (0.5 by default).

## 2) Points and Labels

### 3D Points: `Ddots3d`, `Dballdots3d`, `Dcrossdots3d`

There are three ways to draw 3D points. For the first two, the argument *L* can be either a single 3D point, a list (a table) of 3D points, or a list of lists of 3D points:

- The `g:Ddots3d(L, mark_options, clip)` method. The principle is the same as in the 2D version; the points are drawn in the current line color with the current style. The *mark\_options* argument is an optional string that will be passed as is to the `\draw` instruction (local modifications). The *clip* argument is set to *false* by default; it indicates whether the plot should be clipped to the current 3D window.
- The `g:Dballdots3d(L, color, scale, clip)` method draws the points of *L* as a sphere. The optional *color* argument specifies the color of the sphere (black by default), and the optional *scale* argument allows you to change the size of the sphere (1 by default).
- The `g:Dcrossdots3d(L, color, scale, clip)` method draws the points of *L* as a plane cross. The argument *L* is a list of the form {3D point, normal vector} or { {3D point, normal vector}, {3D point, normal vector}, ...}. For each 3D point, the associated normal vector is used to determine the plane containing the cross. The optional argument *color* specifies the color of the cross (black by default), and the optional argument *scale* allows you to change the size of the cross (1 by default).

```

1 \begin{luadraw}{name=Ddots3d}
2 local g = graph3d:new{viewdir={15,60},bbox=false,size={8,8}}
3 local A, B, C, D = 4*M(1,0,-0.5), 4*M(-1/2,math.sqrt(3)/2,-0.5), 4*M(-1/2,-math.sqrt(3)/2,-0.5), 4*M(0,0,1)
4 local u, v, w = B-A, C-A, D-A
5 -- centres de gravité faces cachées
6 for _, F in ipairs({{A,B,C},{B,C,D}}) do
7   local G, u = isobar3d(F), pt3d.prod(F[2]-F[1],F[3]-F[1])
8   g:Dcrossdots3d({G,u}, "blue", 0.75)
9   g:Dpolyline3d({{F[1],G,F[2]},{G,F[3]}}, "dotted")
10 end
11 -- dessin du tétraèdre construit sur A, B, C et D
12 g:Dpoly(tetra(A,u,v,w), {mode=mShaded,opacity=0.7,color="Crimson"})
13 -- centres de gravité faces visibles
14 for _, F in ipairs({{A,B,D},{A,C,D}}) do
15   local G, u = isobar3d(F), pt3d.prod(F[2]-F[1],F[3]-F[1])
16   g:Dcrossdots3d({G,u}, "blue", 0.75)
17   g:Dpolyline3d({{F[1],G,F[2]},{G,F[3]}}, "dotted")
18 end
19 g:Dballdots3d({A,B,C,D}, "orange") --sommets
20 g:Show()
21 \end{luadraw}

```

Figure 7: A tetrahedron and the centers of gravity of each face

### 3D Labels: Dlabel3d

The method for placing a label in space is:

**g:Dlabel3d(text1, anchor1, args1, text2, anchor2, args2, ...).**

- The arguments *text1*, *text2*,... are strings; they are the labels.
- The arguments *anchor1*, *anchor2*,... are 3D points representing the anchor points of the labels.
- The arguments *args1*, *args2*,... allow you to locally define the label parameters. They are 4-field tables:

```
{ pos=nil, dist=0, dir={dirX,dirY,dep}, node_options="" }
```

- The *pos* field indicates the label's position in the screen plane relative to the anchor point. It can be "N" for north, "NE" for northeast, "NW" for northwest, or "S", "SE", "SW". By default, it is *center*, and in this case, the label is centered on the anchor point.
- The *dist* field is a distance in cm (in the screen plane) that is 0 by default. It is the distance between the label and its anchor point when *pos* is not equal to *center*.
- *dir*=*{dirX,dirY,dep}* is the direction of writing in space (*nil*, the default value, for the default direction). The three values *dirX*, *dirY* and *dep* are three 3D points representing three vectors. The first two indicate the direction of writing, the third a displacement (translation) of the label relative to the anchor point.
- The *node\_options* argument is a string (empty by default) intended to receive options that will be passed directly to tikz in the *node[]* instruction.
- The labels are drawn in the current color of the document text, but the color can be changed with the *node\_options* argument, for example, by setting: *node\_options="color=blue"*.

**Warning:** The options chosen for a label also apply to subsequent labels if they are unchanged.

## 3) Basic Solids (Without Facets)

### Cylinder: Dcylinder

Draw a cylinder with a circular base (right or tilted). Several possible syntaxes:

- Old syntax: **g:Dcylinder(A,V,r,args)** draws a right cylinder, where *A* is a 3d point representing the center of one of the circular faces, *V* is a 3d point, a vector representing the axis of the cone, the center of the opposite circular face is the point  $A + V$  (this face is orthogonal to *V*), and *r* is the radius of the circular base.
- Syntax: **g:Dcylinder(A,r,B,args)** draws a right cylinder, where *A* is a 3d point representing the center of one of the circular faces, *B* is the center of the opposite face, and *r* is the radius. The cylinder is right, meaning that the circular faces are orthogonal to the axis (*AB*).
- For a tilted cylinder: **g:Dcylinder(A,r,V,B,args)**, where *A* is a 3D point representing the center of one of the circular faces, *B* is the center of the opposite circular face, *r* is the radius, and *V* is a non-zero 3D vector orthogonal to the plane of the circular faces.

For all three syntaxes, *args* is a 5-field table for defining plotting options. These options are:

- *mode=mWireframe* or *mGrid* (*mWireframe* by default). In *mWireframe* mode, this is a wireframe drawing; in *mGrid* mode, this is a grid drawing (as if there were facets). *hiddenstyle*, sets the line style for hidden areas (set it to "noline" to hide them). By default, this option has the value of the global variable *Hiddenlinestyle*, which is itself initialized with the value "dotted". *hiddencolor*, sets the color of hidden lines (equal to *edgecolor* by default). *edgecolor*, sets the color of the lines (current color by default). *color=""*, when this option is an empty string (the default value), there is no fill; when it is a color (as a string), there is a fill with a linear gradient.
- *opacity=1*, sets the transparency of the drawing.

### Cone: Dcone

Draw a circular cone (right or inclined). Several possible syntaxes:

- Old syntax: **g:Dcone(A,V,r,args)** draws a right cone, where *A* is a 3D point representing the cone's vertex, *V* is a 3D point, a vector representing the cone's axis, the center of the circular face is point *A + V* (this face is orthogonal to *V*), and *r* is the radius of the circular base.
- Syntax: **g:Dcone(C,r,A,args)** draws a right cone, where *A* is a 3D point representing the cone's vertex, *C* is the center of the circular face, and *r* is the radius. The cone is right, meaning that the circular face is orthogonal to the axis (*AC*).
- For a tilted cone: **g:Dcone(C,r,V,A,args)**, where *A* is a 3D point representing the cone's vertex, *C* is the center of the circular face, *r* is the radius, and *V* is a non-zero 3D vector orthogonal to the plane of the circular face.

For all three syntaxes, *args* is a 5-field table for defining plotting options. These options are:

- *mode=mWireframe* or *mGrid* (*mWireframe* by default). In *mWireframe* mode, this is a wireframe drawing; in *mGrid* mode, this is a grid drawing (as if there were facets). *hiddenstyle*, sets the line style for hidden areas (set it to "noline" to hide them). By default, this option has the value of the global variable *Hiddenlinestyle*, which is itself initialized with the value "dotted". *hiddencolor*, sets the color of hidden lines (equal to *edgecolor* by default). *edgecolor*, sets the color of the lines (current color by default). *color=""*, when this option is an empty string (the default value), there is no fill; when it is a color (as a string), there is a fill with a linear gradient.
- *opacity=1*, sets the transparency of the drawing.

### Frustum: Dfrustum

Draw a truncated cone with a circular base (right or slanted). Two possible syntaxes: The method **g:Dfrustum(A,V,R,r,args)** draws a truncated cone with circular bases.

- The syntax: **g:Dfrustum(A,R,r,V,args)** for a right truncated cone, *A* is a 3D point representing the center of the face with radius *R*, *V* is a 3D vector representing the axis of the truncated cone, the center of the second circular face is the point *A + V*, and its radius is *r* (the faces are orthogonal to *V*). When *R = r* we simply have a cylinder.
- Syntax: **g:Dfrustum(A,R,r,V,B,args)** for a tilted cone frustum, *A* is a 3D point representing the center of the face with radius *R*, *V* is a 3D vector representing a normal vector to the circular faces, the center of the second circular face is point *B*, and its radius is *r*. When *R = r* we have a tilted cylinder.

In both cases, *args* is a 5-field table for defining plotting options. These options are:

- *mode=mWireframe* or *mGrid* (*mWireframe* by default). In *mWireframe* mode, this is a wireframe drawing; in *mGrid* mode, this is a grid drawing (as if there were facets). *hiddenstyle*, sets the line style for hidden areas (set it to "noline" to hide them). By default, this option has the value of the global variable *Hiddenlinestyle*, which is itself initialized with the value "dotted". *hiddencolor*, sets the color of hidden lines (equal to *edgecolor* by default). *edgecolor*, sets the color of the lines (current color by default). *color=""*, when this option is an empty string (the default value), there is no fill; when it is a color (as a string), there is a fill with a linear gradient.
- *opacity=1*, sets the transparency of the drawing.

**Sphere: Dsphere**

The **g:Dsphere(A,r,args)** method draws a sphere.

- *A* is a 3D point representing the center of the sphere.
- *r* is the radius of the sphere.
- *args* is a 5-field table for defining drawing options. These options are:
  - *mode*=*mWireframe* or *mGrid* or *mBorder* (*mWireframe* by default). In *mWireframe* mode, the outline (circle) and the equator are drawn; in *mGrid* mode, the outline with meridians and spindles (grid) is drawn; and in *mBorder* mode, the outline only is drawn.
  - *hiddenstyle*, defines the line style for hidden areas (set it to "noline" to hide them). By default, this option has the value of the global variable *Hiddenlinestyle*, which is itself initialized with the value "dotted".
  - *hiddencolor*, defines the color of hidden lines (equal to *edgecolor* by default).
  - *color*="", when this option is an empty string (the default value), there is no fill; when it is a color (as a string), there is a fill with a "ball color".
  - *opacity*=1, defines the transparency of the drawing.
  - *edgestyle*, defines the line style for visible edges; by default, it is the current style.
  - *edgecolor*, sets the color of the visible edges (current color by default).
  - *edgewidth*, sets the thickness of the visible edges in tenths of a point (current thickness by default).

```

Figure 8: Cylinders, Cones, and Spheres

## V Faceted Solids

### 1) Definition of a Solid

There are two ways to define a solid:

1. As a list (table) of facets. A facet is itself a list of 3D points (at least 3) that are coplanar and unaligned, which are the vertices. Facets are assumed to be convex and are oriented by the order of appearance of the vertices. That is, if  $A$ ,  $B$ , and  $C$  are the first three vertices of a facet  $F$ , then the facet is oriented with the normal vector  $\vec{AB} \wedge \vec{AC}$ . If this normal vector is directed toward the observer, then the facet is considered visible. In the definition of a solid, the normal vectors to the facets must be directed **outside** the solid for the orientation to be correct.
2. In the form of a **polyhedron**, that is to say a table with two fields, a first field called *vertices* which is the list of vertices of the polyhedron (3d points), and a second field called *facets* which is the list of facets, but here, in the definition of the facets, the vertices are replaced by their index in the *vertices* list. The facets are oriented in the same way as before.

For example, let's consider the four points  $A = M(-2, -2, 0)$ ,  $B = M(3, 0, 0)$ ,  $C = M(-2, 2, 0)$ , and  $D = M(0, 0, 4)$ . We can then define the tetrahedron constructed on these four points:

- either as a list of facets:  $T = \{\{A, B, D\}, \{B, C, D\}, \{C, A, D\}, \{A, C, B\}\}$  (pay attention to the orientation),
- or as a polyhedron:  $T = \{\text{vertices} = \{A, B, C, D\}, \text{facets} = \{\{1, 2, 4\}, \{2, 3, 4\}, \{3, 1, 4\}, \{1, 3, 2\}\}\}$ .

### 2) Drawing a Polyhedron: Dpoly

The function **gDpoly(P,options)** allows you to represent the polyhedron  $P$  (using the naive painter's algorithm). The argument *options* is a table containing the options:

- **mode=**: Sets the representation mode.
  - **mode=mWireframe**: Wireframe mode, draws both visible and hidden edges.
  - **mode=mFlat**: Draws solid-color faces, as well as visible edges.
  - **mode=mFlatHidden**: Draws solid-color faces, visible edges, and hidden edges.

- *mode=mShaded*: Draws the faces in shaded color based on their inclination, as well as the visible edges. This is the default mode.
  - *mode=mShadedHidden*: Draws the faces in shaded color based on their inclination, with both visible and hidden edges.
  - *mode=mShadedOnly*: Draws the faces in shaded color based on their inclination, but not the edges.
- **contrast**: This is a number that defaults to 1. This number allows you to accentuate or diminish the shade of the facet colors in the *mShaded*, *mShadedHidden*, and *mShadedOnly* modes.
  - **edgestyle**: This is a string that defines the line style of the edges. This is the current style by default.
  - **edgecolor** : is a string that defines the edge color. This is the current line color by default.
  - **hiddenstyle** : is a string that defines the line style of hidden edges. By default, this is the value contained in the global variable *Hiddenlinestyle* (which itself is "dotted" by default).
  - **hiddencolor** : is a string that defines the color of hidden edges. This is the current line color by default.
  - **edgewidth** : line thickness of edges in tenths of a point. This is the current thickness by default.
  - **opacity** : a number between 0 and 1 that allows you to set transparency or not on the facets. The default value is 1, which means no transparency.
  - **backcull**: Boolean that defaults to false. When true, facets considered invisible (normal vectors not directed towards the observer) are not displayed. This option is useful for convex polyhedra because it reduces the number of facets to draw.
  - **twoside**: Boolean that defaults to true, meaning that both sides of the facets (inner and outer) are distinguished; the two sides will not have exactly the same color.
  - **color**: String defining the fill color of the facets; it is "white" by default.
  - **usepalette** (*nil* by default), this option allows you to specify a color palette for painting the facets as well as a calculation mode, the syntax is: *usepalette = {palette,mode}*, where *palette* designates a table of colors which are themselves tables of the form  $\{r,g,b\}$  where *r*, *g* and *b* are numbers between 0 and 1, and *mode* which is a string that can be either "x", or "y", or "z". In the first case for example, the facets with the center of gravity of minimum abscissa have the first color of the palette, the facets with the center of gravity of maximum abscissa have the last color of the palette, for the others, the color is calculated according to the abscissa of the center of gravity by linear interpolation.

```

1 \begin{luadraw}{name=tetra_coupe}
2 local g = graph3d:new{viewdir={10,60},bbox=false, size={10,10}, bg="gray!30"}
3 local A,B,C,D = M(-2,-4,-2),M(4,0,-2),M(-2,4,-2),M(0,0,2)
4 local T = tetra(A,B-A,C-A,D-A) -- tetrahedron with vertices A, B, C, D
5 local plan = {Origin, -vecK} -- sectional plan
6 local T1, T2, section = cutpoly(T,plan) -- we cut the tetrahedron
7 -- T1 is the resulting polyhedron in the half-space containing -vecK
8 -- T2 is the resulting polyhedron in the other half-space
9 -- section is a facet (it's the cut)
10 g:Dpoly(T1,{color="Crimson", edgecolor="white", opacity=0.8, edgewidth=8})
11 g:Filloptions("bdiag","Navy"); g:Dpolyline3d(section,true,"draw=none")
12 g:Dpoly(shift3d(T2,2*vecK), {color="Crimson", edgecolor="white", opacity=0.8, edgewidth=8})
13 g:Dballdots3d({A,B,C,D+2*vecK}) -- we drew T2 translated with the vector 2*vecK
14 g:Show()
15 \end{luadraw}

```

Figure 9: Section of a tetrahedron by a plane

### 3) Polyhedron Construction Functions

The following functions return a polyhedron, that is, a table with two fields: a first field called *vertices*, which is the list of the polyhedron's vertices (3D points), and a second field called *facets*, which is the list of facets. However, in the definition of facets, the vertices are replaced by their index in the *vertices* list.

- **tetra(*S*,*v1*,*v2*,*v3*)** returns the tetrahedron with vertices *S* (3D point), *S* + *v1*, *S* + *v2*, *S* + *v3*. The three vectors *v1*, *v2*, *v3* (3D points) are assumed to be forward-directed.
- **parallelep(*A*,*v1*,*v2*,*v3*)** returns the parallelepiped constructed from vertex *A* (3d point) and three vectors *v1*, *v2*, *v3* (3d points) assumed to be in the forward direction.
- **prism(*base*,*vector*,*open*)** returns a prism. The argument *base* is a list of 3d points (one of the two bases of the prism). *vector* is the translation vector (3d point) used to obtain the second base. The optional argument *open* is a Boolean indicating whether the prism is open or not (false by default). If it is open, only the lateral facets are returned. The *base* must be oriented by the *vector*.
- **pyramid(*base*,*vertex*,*open*)** returns a pyramid. The argument *base* is a list of 3D points, and *vertex* is the apex of the pyramid (3D point). The optional argument *open* is a Boolean indicating whether the pyramid is open or not (false by default). If it is open, only the side facets are returned. The *base* must be vertex-oriented.
- **regular\_pyramid(*n*,*side*,*height*,*open*,*center*,*axis*)** returns a regular pyramid. *n* is the number of sides of the base, the argument *side* is the length of a side, and *height* is the height of the pyramid. The optional argument *open* is a Boolean indicating whether the pyramid is open or not (false by default). If it is open, only the lateral facets are returned. The optional argument *center* is the center of the base (*Origin* by default), and the optional argument *axis* is a direction vector of the pyramid axis (*vecK* by default).
- **truncated\_pyramid(*base*,*vertex*,*height*,*open*)** returns a truncated pyramid; the argument *base* is a list of 3D points; *vertex* is the apex of the pyramid (3D point). The argument *height* is a number indicating the height from the base where the truncation occurs; this is parallel to the plane of the base. The optional argument *open* is a boolean indicating whether the pyramid is open or not (false by default). If it is open, only the lateral facets are returned. The base must be oriented by the vertex.
- **cylinder(*A*,*V*,*R*,*nbfacet*,*open*)** returns a cylinder of radius *R*, with axis {*A*,*V*}, where *A* is a 3D point, the center of one of the circular bases, and *V* is a non-zero 3D vector such that the center of the second base is the point *A* + *V*. The optional argument *nbfacet* is 35 by default (number of lateral facets). The optional argument *open* is a Boolean indicating whether the cylinder is open or not (false by default). If it is open, only the lateral facets are returned.
- **cylinder(*A*,*R*,*B*,*nbfacet*,*open*)** returns a cylinder of radius *R*, axis (*AB*) where *A* is a 3D point, the center of one of the circular bases and *B* the center of the second base. The cylinder is right. The optional argument *nbfacet* is 35 by

default (number of lateral facets). The optional argument *open* is a Boolean indicating whether the cylinder is open or not (false by default). If it is open, only the lateral facets are returned.

- **cylinder(A,R,V,B,nbfacet,open)** returns a cylinder of radius  $R$ , axis ( $A$ ) where  $A$  is a 3d point, center of one of the circular bases,  $B$  is the center of the second base, and  $V$  is a 3d vector normal to the plane of the circular bases (the cylinder can therefore be tilted). The optional argument *nbfacet* is 35 by default (number of lateral facets). The optional argument *open* is a boolean indicating whether the cylinder is open or not (false by default). If it is open, only the lateral facets are returned.
- **cone(A,V,R,nbfacet,open)** returns a cone with vertex  $A$  (3d point), axis  $\{A,V\}$ , and circular base, the circle with center  $A + V$  and radius  $R$  (in a plane orthogonal to  $V$ ). The optional argument *nbfacet* is 35 by default (number of lateral facets). The optional argument *open* is a boolean indicating whether the cone is open or not (false by default). If it is open, only the lateral facets are returned.
- **cone(C,R,A,nbfacet,open)** returns a cone with vertex  $A$  (3d point),  $C$  is the circular base center, and  $R$  is its radius (in a plane orthogonal to the  $(AC)$  axis). The optional argument *nbfacet* is 35 by default (number of lateral facets). The optional argument *open* is a Boolean indicating whether the cone is open or not (false by default). If it is open, only the lateral facets are returned.
- **cone(C,R,V,A,nbfacet,open)** returns a cone with vertex  $A$  (3d point),  $C$  is the circular base center,  $R$  is its radius, and the base is in a plane orthogonal to  $V$  (3d vector). The  $(AC)$  axis is therefore not necessarily orthogonal to the circular face (tilted cone). The optional argument *nbfacet* is 35 by default (number of lateral facets). The optional argument *open* is a Boolean indicating whether the cone is open or not (false by default). If it is open, only the lateral facets are returned.
- **frustum(C,R,r,V,nbfacet,open)** returns a right frustum. Point  $C$  (point 3d) is the center of the circular base of radius  $R$ , and vector  $V$  directs the axis of the frustum. The center of the other circular base is point  $C + V$ , and its radius is  $r$  (the bases are orthogonal to  $V$ ). The optional argument *nbfacet* is 35 by default (number of lateral facets). The optional argument *open* is a Boolean indicating whether the frustum is open or not (false by default). If it is open, only the lateral facets are returned.
- **frustum(C,R,r,V,A,nbfacet,open)** returns a right frustum of a cone. Point  $C$  (3d point) is the center of the circular base of radius  $R$ , the center of the other circular base is point  $A$ , and its radius is  $r$ . The bases are orthogonal to vector  $V$ , but not necessarily orthogonal to axis  $(AC)$ . The optional argument *nbfacet* is 35 by default (number of lateral facets). The optional argument *open* is a Boolean indicating whether the frustum is open or not (false by default). If it is open, only the lateral facets are returned.
- **sphere(A,R,nbu,nbv)** returns the sphere with center  $A$  (3d point) and radius  $R$ . The optional argument *nbu* represents the number of spindles (36 by default) and the optional argument *nbv* the number of parallels (20 by default).

Figure 11: Hyperbola: cone-plane intersection

In this example, cones  $C_1$  and  $C_2$  are defined as polyhedra to determine their intersection with plane  $P$ , but not to draw them. The method **g:Intersection3d(C1,P)** returns the intersection of polyhedron  $C_1$  with plane  $P$  as a two-field table: one field named *visible* that contains a 3D polygonal line representing the visible "edges" (segments) of the intersection (i.e., those that are on a visible facet of  $C_1$ ), and another field named *hidden* that contains a 3D polygonal line representing the hidden "edges" of the intersection (i.e., those that are on a non-visible facet of  $C_1$ ). The method **g:Dedges** can be used to draw these types of objects.

#### 4) Reading from an obj file

The function `red_obj_file(file)`<sup>1</sup> allows you to read the contents of the file *obj* designated by the string *file*. The function reads the vertex definitions (lines beginning with *v* ), and the lines defining the facets (lines beginning with *f* ). The other lines are ignored. The function returns a sequence consisting of the polyhedron, followed by a list of four real numbers  $\{x1,x2,y1,y2,z1,z2\}$  representing the 3D bounding box of the polyhedron.

```

1 \begin{luadraw}{name=lecture_obj}
2 local P,bbox = read_obj_file("obj/nefertiti.obj")
3 local g = graph3d:new{window3d=bbox,window={-6,5,-7,7},viewdir=perspective("central",35,65,20),
4   margin={0,0,0,0}, size={10,10}, bg="LightGray"}
5 g:Dpoly(P, {usepalette={palAutumn,"z"},mode=mShadedOnly})
6 g:Show()
7 \end{luadraw}

```

Figure 13: Mask of Nefertiti

#### 5) Drawing a List of Facets: Dfacet and Dmixfacet

There are two possible methods:

1. For a solid *S* in the form of a list of facets (with 3D points), the method is:

**`g:Dfacet(S,options)`**

where *S* is the list of facets and *options* is a table defining the options. These are:

- `mode=`: Sets the representation mode.
  - `mode=mWireframe`: Wireframe mode, draws only the edges.
  - `mode=mFlat` or `mFlatHidden`: Draws the faces in a solid color, as well as the edges.
  - `mode=mShaded` or `mShadedHidden`: The faces are drawn in shaded color based on their inclination, as well as the edges. The default mode is 3.
  - `mode=mShadedOnly`: The faces are drawn in shaded color based on their inclination, but not the edges.
- `contrast`: This is a number that defaults to 1. This number allows you to accentuate or diminish the shade of the facet colors in the `mShaded`, `mShadedHidden`, and `mShadedOnly` modes.

<sup>1</sup>This function is a contribution by Christophe BAL.

- **edgestyle**: This is a string that defines the line style of the edges. This is the current style by default.
- **edgecolor**: This is a string that defines the color of the edges. This is the current default line color.
- **hiddenstyle**: is a string that defines the line style of the hidden edges. By default, this is the value contained in the global variable *Hiddenlinestyle* (which itself is "dotted" by default).
- **hiddencolor**: is a string that defines the color of the hidden edges. This is the current default line color.
- **edgewidth**: line thickness of the edges in tenths of a point. This is the current default thickness.
- **opacity**: a number between 0 and 1 that allows you to set transparency or not on the facets. The default value is 1, which means no transparency.
- **backcull**: a boolean that defaults to false. When set to true, facets considered invisible (normal vector not directed towards the observer) are not displayed. This option is useful for convex polyhedra because it reduces the number of facets to be drawn.
- **clip**: Boolean that defaults to false. When set to true, the facets are clipped by the 3D window.
- **twoside**: Boolean that defaults to true, meaning that both sides of the facets (inner and outer) are distinguished; the two sides will not have exactly the same color.
- **color**: String defining the fill color of the facets; it is "white" by default.
- **usepalette** (*nil* by default), this option allows you to specify a color palette for painting the facets as well as a calculation mode, the syntax is: *usepalette = {palette,mode}*, where *palette* designates a table of colors which are themselves tables of the form  $\{r,g,b\}$  where *r*, *g* and *b* are numbers between 0 and 1, and *mode* which is a string that can be either "x", or "y", or "z". In the first case for example, the facets with the center of gravity of minimum abscissa have the first color of the palette, the facets with the center of gravity of maximum abscissa have the last color of the palette, for the others, the color is calculated according to the abscissa of the center of gravity by linear interpolation.

2. For multiple facet lists in the same drawing, the method is:

**g:Dmixfacet(S1,options1, S2,options2, ...)**

where *S1*, *S2*, ... are facet lists, and *options1*, *options2*, ... are the corresponding options. The options in one facet list also apply to the following ones if they are not changed. These options are identical to the previous method.

This method is useful for drawing multiple solids together, provided there are no intersections between the objects, as these are not handled here.

```

1  \begin{luadraw}{name=courbes_niv}
2  local cos, sin = math.cos, math.sin, math.pi
3  local g = graph3d:new{window3d={0,5,0,10,0,11}, adjust2d=true, size={10,10},
4  ← viewdir=perspective("central",220,60,15,M(2.5,5,5.5))}
5  g:Labelsize("footnotesize")
6  local S = cartesian3d(function(u,v) return (u+v)/(2+cos(u)*sin(v)) end,0,5,0,10,{30,30})
7  local n = 10 -- nombre de niveaux
8  local Colors = getpalette(palGasFlame,n,true) -- liste de 10 couleurs au format table
9  local niv, S1 = {}
10 for k = 1, n do
11     S1, S = cutfacet(S,{M(0,0,k),-vecK}) -- section de S avec le plan z=k
12     insert(niv,{S1, {color=Colors[k],mode=mShaded,edgewidth=0.5}}) -- S1 est la partie sous le plan et S au dessus
13 end
14 insert(niv,{S, {color=Colors[n+1]}}) -- insertion du dernier niveau
15 -- niv est une liste du type {facettes1, options1, facettes2, options2, ...}
16 g:Dboxaxes3d({grid=true, gridcolor="gray",fillcolor="lightgray"})
17 g:Dmixfacet(table.unpack(niv))
18 for k = 1, n do
19     g:Dballdots3d( M(5,0,k), rgb(Colors[k]))
20 end
21 g:Dlabel("$z=\frac{x+y}{2+\cos(x)\sin(y)}$", Z((g:Xinf()+g:Xsup())/2, g:Yinf()), {pos="N"})
22 g:Show()
23 \end{luadraw}

```

Figure 14: Example of contour lines on a surface

## 6) Functions for Constructing Facet Lists

The following functions return a solid as a list of facets (with 3D points).

### surface()

The function **surface(f,u1,u2,v1,v2,grid)** returns the surface parameterized by the function  $f: (u, v) \mapsto f(u, v) \in \mathbb{R}^3$ . The range for parameter  $u$  is given by  $u1$  and  $u2$ . The range for parameter  $v$  is given by  $v1$  and  $v2$ . The optional parameter *grid* is {25,25} by default; it defines the number of points to calculate for parameter  $u$  followed by the number of points to calculate for parameter  $v$ .

There are two variants for surfaces:

### cartesian3d()

The function **cartesian3d(f,x1,x2,y1,y2,grid,addWall)** returns the Cartesian surface with equation  $z = f(x, y)$  where  $f: (x, y) \mapsto f(x, y) \in \mathbb{R}$ . The interval for  $x$  is given by  $x1$  and  $x2$ . The interval for  $y$  is given by  $y1$  and  $y2$ . The optional parameter *grid* is {25,25} by default; it defines the number of points to calculate for  $x$  followed by the number of points to calculate for  $y$ . The parameter *addWall* is 0 or "x", or "y", or "xy" (0 by default). When this option is set to "x" (or "xy"), the function returns, after the list of facets composing the surface, a list of separating facets (walls or partitions) between each "layer" of facets. A layer corresponds to two consecutive values of the parameter  $x$ . With the value "y" (or "xy"), it is a list of separating facets (walls) between each "layer" corresponding to two consecutive values of the parameter  $y$ . This option can be useful with the **g:Dscene3d** method (only), because the separating partitions form a partition of space isolating the facets of the surface, which avoids unnecessary intersection calculations between them. This is particularly the case with non-convex surfaces.

For example, here is the code for figure 1:

```
1 \begin{luadraw}{name=point_col}
2 local g = graph3d:new{window3d={-2,2,-2,2,-4,4}, window={-3.5,3,-5,5}, size={8,9,0}, viewdir={120,60}}
3 local S = cartesian3d(function(u,v) return u^2-v^2 end, -2,2,-2,2,{20,20}) -- surface of equation z=x^2-y^2
4 local Tx = g:Intersection3d(S, {Origin,vecI}) --intersection of S with the yOz plane
5 local Ty = g:Intersection3d(S, {Origin,vecJ}) --intersection of S with the xOz plane
6 g:Dboxaxes3d({grid=true,gridcolor="gray",fillcolor="LightGray",drawbox=true})
7 g:Dfacet(S,{mode=mShadedOnly,color="ForestGreen"}) -- surface drawing
8 g:Dedges(Tx, {color="Crimson", hidden=true, width=8}) -- intersection with yOz
```

```

9 g:Dedges(Ty, {color="Navy",hidden=true, width=8}) -- intersection with xOz
10 g:Dpolyline3d( {M(2,0,4),M(-2,0,4),M(-2,0,-4)}, "Navy,line width=.8pt")
11 g:Dpolyline3d( {M(0,-2,4),M(0,2,4),M(0,2,-4)}, "Crimson,line width=.8pt")
12 g:Show()
13 \end{luadraw}

```

### cylindrical\_surface()

The function **cylindrical\_surface**(*r,z,u1,u2,theta1,theta2,grid,addWall*) returns the surface parameterized as cylindrical by  $r(u, \theta)$ ,  $\theta$ ,  $z(u, \theta)$ . The arguments *r* and *z* are therefore two real-valued functions of *u* and  $\theta$ . The interval for *u* is given by *u1* and *u2*. The interval for  $\theta$  is given by *theta1* and *theta2* (in radians). The optional parameter *grid* is {25,25} by default; it defines the number of points to calculate for *u* followed by the number of points to calculate for *v*. The parameter *addWall* is 0 or "v" or "z" or "vz" (0 by default). When this option is "v" or "vz", the function returns, after the list of facets composing the surface, a list of separating facets (walls or partitions) between each "layer" of facets, a layer corresponds to two consecutive values of the angle  $\theta$ <sup>2</sup>. When this option is set to "z" or "vz", the function returns, after the list of facets composing the surface, a list of separating facets (walls or partitions) between each "layer" of facets. A layer corresponds to two consecutive values of the dimension  $z$ <sup>3</sup>, the values of *z* are calculated from the values of the parameter *u* and with the value *theta1*. This is useful when *z* only depends on *u* (and therefore not on *theta*). This option can be useful with the **g:Dscene3d** method (only), because the separating partitions form a partition of space isolating the surface facets, which avoids unnecessary intersection calculations between them. This is particularly the case with non-convex surfaces.

```

1 \begin{luadraw}{name=surface_with_addWall}
2 local pi, ch, sh = math.pi, math.cosh, math.sinh
3 local g = graph3d:new{window3d={-4,4,-4,4,-5,5}, window={-10,10,-4,4}, size={10,10}, viewdir={60,60}}
4 g:Labelsize("footnotesize")
5 local S,wall = cartesian3d(function(x,y) return x^2-y^2 end,-2,2,-2,2,nil,"xy")
6 g:Saveattr(); g:Viewport(-10,0,-4,4); g:Coordsystem(-4.5,4.5,-4.5,4.75)
7 g:Dscene3d(
8   g:addWall(wall), -- 2 facet cutouts with this instruction, and 529 facet cutouts without it
9   g:addFacet(S,{color="SteelBlue"}),
10  g:addAxes(Origin,{arrows=1}) )
11 g:Restoreattr()
12 g:Saveattr(); g:Viewport(0,10,-4,4); g:Coordsystem(-5,5,-5,5)
13 local r = function(u,v) return ch(u) end
14 local z = function(u,v) return sh(u) end
15 S,wall = cylindrical_surface(r,z,2,-2,-pi,pi,{25,51},"zv")
16 g:Dscene3d(
17   g:addWall(wall), -- 13 facet cutouts with this instruction, and more than 17000 facet cutouts without it ...
18   g:addFacet(S,{color="Crimson"}),
19   g:addAxes(Origin,{arrows=1}) )
20 g:Restoreattr()
21 g:Show()
22 \end{luadraw}

```

Figure 15: Surfaces using the *addWall* option

<sup>2</sup>These partitions are in fact planes of equation  $\theta = \text{constant}$

<sup>3</sup>These partitions are actually planes with the equation  $z = \text{constant}$

**curve2cone()**

The function **curve2cone(f,t1,t2,S,args)** constructs a cone with vertex  $S$  (3d point) and the base curve parametrized by  $f: t \mapsto f(t) \in \mathbf{R}^3$  on the interval defined by  $t1$  et  $t2$ . The argument *args* is an optional table to define the options, which are:

- **nbdots** which represents the minimum number of points on the curve to calculate (15 by default).
- **ratio** which is a number representing the homothety ratio (centered at vertex  $S$ ) to construct the other part of the cone. By default, *ratio* is 0 (no second part).
- **nbddiv** which is a positive integer indicating the number of times the interval between two consecutive values of the parameter  $t$  can be bisected (dichotomized) when the corresponding points are too far apart. By default, *nbddiv* is 0.

This function returns a list of facets, followed by a 3D polygonal line representing the edges of the cone.

```

1 \begin{luadraw}{name=curve2cone}
2 local cos, sin, pi = math.cos, math.sin, math.pi
3 local g = graph3d:new{ window3d={-2,2,-4,4,-3,3},window={-5.5,5.5,-5.5,5},size={10,10},viewdir=perspective("central")}
4 local f = function(t) return M(2*cos(t),4*sin(t),-3) end -- ellipse dans le plan z=-3
5 local C, bord = curve2cone(f,-pi,pi,Origin,{nbddiv=2, ratio=-1})
6 g:Dboxaxes3d({grid=true,gridcolor="gray",fillcolor="LightGray"})
7 g:Dpolyline3d(bord[1],"red,line width=2.4pt") -- bord inférieur
8 g:Dfacet(C, {mode=mShadedOnly,color="LightBlue"}) -- cône
9 g:Dpolyline3d(bord[2],"red,line width=0.8pt") -- bord supérieur
10 g:Show()
11 \end{luadraw}

```

Figure 16: Elliptical Cone Example

**curve2cylinder()**

The function **curve2cylinder(f,t1,t2,V,args)** constructs a cylinder with axis directed by the vector  $V$  (3d point) and with a base parameterized by  $f: t \mapsto f(t) \in \mathbf{R}^3$  on the interval defined by  $t1$  and  $t2$ . The second base is the translation of the first with the vector  $V$ . The argument *args* is an optional table to define the options, which are:

- **nbdots** which represents the minimum number of points on the curve to calculate (15 by default).
- **nbddiv** which is a positive integer indicating the number of times the interval between two consecutive values of the parameter  $t$  can be cut in two (dichotomized) when the corresponding points are too far apart. By default, *nbddiv* is 0.

This function returns a list of facets, followed by a 3D polygonal line representing the edges of the cylinder.

```

1 \begin{luadraw}{name=curve2cylinder}
2 local cos, sin, pi = math.cos, math.sin, math.pi
3 local g = graph3d:new{
4   ~ window3d={-5,5,-5,5,-4,4},window={-9,8,-10.5,5.5},viewdir=perspective("central",39,64),size={10,10}}
5 local f = function(t) return M(4*cos(t)-cos(4*t),4*sin(t)-sin(4*t),-4) end -- courbe dans le plan z=-3
6 local V = 8*vecK
7 local C = curve2cylinder(f,-pi,pi,V,{nbdots=25,nbdiv=2})
8 local plan = {M(0,0,2), -vecK} -- plan de coupe z=2

15 g:Show()
16 \end{luadraw}

```

Figure 17: Section of a non-circular cylinder

### line2tube()

The function **line2tube(L,r,args)** constructs (as a list of facets) a tube centered on  $L$ , which must be a 3D polygonal line (list of 3D points or list of lists of 3D points). The argument  $r$  represents the radius of this tube. The argument  $args$  is a table for defining the options, which are:

- **nbfacet**: number indicating the number of lateral facets of the tube (3 by default).
- **close**: boolean indicating whether the polygonal line  $L$  should be closed (false by default).
- **hollow**: boolean indicating whether both ends of the tube should be open or not (false by default). When the **close** option is set to true, the **hollow** option is automatically set to true.
- **addwall**: A number that is 0 or 1 (0 by default). When this option is 1, the function returns, after the list of facets composing the tube, a list of separating facets (walls) between each "section" of the tube, which can be useful with the **g:Dscene3d** method (only).

The function **section2tube(section,L,args)** also constructs a tube centered on  $L$ , which must be a list of 3D points. The argument  $section$  must be a facet centered on the first point of  $L$ ; it represents a section of the tube to be constructed. The argument  $args$  is an array for defining the options, which are:

- **close**: Boolean indicating whether the polygonal line  $L$  should be closed (false by default).
- **hollow**: Boolean indicating whether both ends of the tube should be open or not (false by default). When the **close** option is true, the **hollow** option automatically takes the value true.
- **addwall**: A number that is either 0 or 1 (0 by default). When this option is set to 1, the function returns, after the list of facets composing the tube, a list of separating facets (walls) between each "section" of the tube, which can be useful with the **g:Dscene3d** method (only).

```

1 \begin{luadraw}{name=line2tube_section2tube}
2 local g = graph3d:new{window={-5,6,-4.5,8}, viewdir={45,60}, margin={0,0,0,0}, size={10,10}}

12 g:Show()
13 \end{luadraw}

```

Figure 18: Example with line2tube and section2tube

### rotcurve()

The function **rotcurve(p,t1,t2,axis,angle1,angle2,args)** constructs, as a list of facets, the surface swept by the curve parameterized by  $p: t \mapsto p(t) \in \mathbf{R}^3$  over the interval defined by  $t1$  and  $t2$ , by rotating it around  $axis$  (which is a table of the form {point3d, 3d vector} representing an oriented line in space), by an angle ranging from  $angle1$  (in degrees) to  $angle2$ . The  $args$  argument is a table for defining the options, which are:

- **grid**: table consisting of two numbers, the first being the number of points calculated for the  $t$  parameter, and the second being the number of points calculated for the angular parameter. By default, the value of **grid** is {25,25}.
- **addwall**: number equal to 0, 1, or 2 (0 by default). When this option is set to 1, the function returns, after the list of facets composing the surface, a list of separating facets (walls) between each "layer" of facets (a layer corresponds to two consecutive values of the  $t$  parameter), and with a value of 2, it is a list of separating facets (walls) between each

rotation "slice" (a layer corresponds to two consecutive values of the angular parameter; this is useful when the curve is in the same plane as the rotation axis). This option can be useful with the **g:Dscene3d** method (only).

```

1 \begin{luadraw}{name=rotcurve}
2 local cos, sin, pi, i = math.cos, math.sin, math.pi, cpx.I
3 local g = graph3d:new{viewdir={30,60},size={10,10}}
4 local p = function(t) return M(0,sin(t)+2,t) end -- curve in the plane yOz
5 local axe = {Origin,vecK}
6 local S = rotcurve(p,pi,-pi,axe,0,360,{grid={25,35}})
7 local visible, hidden = g:Classifyfacet(S)
8 g:Dfacet(hidden, {mode=mShadedOnly,color="cyan"})
9 g:Dline3d(axe,"red,line width=1.2pt")
10 g:Dfacet(visible, {mode=5,color="cyan"})
11 g:Dline3d(axe,"red,line width=1.2pt,dashed")
12 g:Dparametric3d(p,{t={-pi,pi}},draw_options="red,line width=1.2pt")
13 g:Show()
14 \end{luadraw}

```

Figure 19: Example with rotcurve

**Note** : If the surface orientation does not seem correct, simply swap the parameters  $t1$  and  $t2$ , or  $angle1$  and  $angle2$ .

### rotline()

The function **rotline(L,axis,angle1,angle2,args)** constructs, as a list of facets, the surface swept by the list of 3d points  $L$  by rotating it around  $axis$  (which is a table of the form {point3d, 3d vector} representing an oriented line in space), through an angle ranging from  $angle1$  (in degrees) to  $angle2$ . The  $args$  argument is a table for defining the options, which are:

- **nbdots**: This is the number of points calculated for the angular parameter. By default, the value of **nbdots** is 25.
- **close**: A boolean indicating whether  $L$  should be closed (false by default).
- **addwall**: A number equal to 0, 1, or 2 (0 by default). When this option is set to 1, the function returns, after the list of facets composing the surface, a list of separating facets (walls) between each "layer" of facets (a layer corresponds to two consecutive points in the list  $L$ ), and with a value of 2, it is a list of separating facets (walls) between each rotation "slice" (a layer corresponds to two consecutive values of the angular parameter; this is useful when the curve is in the same plane as the rotation axis). This option can be useful with the **g:Dscene3d** method (only).

```

1 \begin{luadraw}{name=rotline}
2 local g = graph3d:new{window={-4,4,-4,4},size={10,10}}
3 local L = {M(0,0,4),M(0,4,0),M(0,0,-4)} -- list of points in the yOz plane
4 local axe = {Origin,vecK}
5 local S = rotline(L,axe,0,360,{nbdots=5}) -- point 1 and point 5 are confused
6 g:Dfacet(S,{color="Crimson",edgecolor="Gold",opacity=0.8})
7 g:Show()
8 \end{luadraw}

```

Figure 20: Example with rotline

## 7) Edges of a solid

An "edge" object is a table with two fields: one field named *visible* that contains a 3D polygonal line corresponding to the visible edges, and another field named *hidden* that contains a 3D polygonal line corresponding to the hidden edges.

- The method **g:Edges(P)**, where *P* is a polyhedron, returns the edges of *P* as an "edge" object. An edge of *P* is visible when it belongs to at least one visible face.
- The method **g:Intersection3d(P,plane)**, where *P* is a polyhedron or a list of facets, returns as an "edge" object the intersection between *P* and the plane represented by *plane* (it is a table of the form {A,u} where *A* is a point on the plane and *u* is a normal vector, so they are two 3d points).
- The method **g:Dedges(edges,options)** allows you to draw *edges*, which must be an "edge" object. The argument *options* is a table defining the options, these are:
  - **hidden**: Boolean indicating whether hidden edges should be drawn (false by default).
  - **visible**: Boolean indicating whether visible edges should be drawn (true by default).
  - **clip**: Boolean indicating whether edges should be clipped by the 3D window (false by default).
  - **hiddenstyle**: String defining the line style of hidden edges. By default, this option contains the value of the global variable *Hiddenlinestyle* (which defaults to "dotted").
  - **hiddencolor**: String defining the color of hidden edges. By default, this option contains the same color as the **color** option.
  - **style**: String defining the line style of visible edges. By default, this option contains the current line drawing style.

- **color**: String defining the color of the visible edges. By default, this option contains the current line drawing color.
- **width**: Number representing the line thickness of the edges (in tenths of a point). By default, this variable contains the current line drawing thickness.

- **Complement:**

- The function **facetedges(F)**, where  $F$  is a list of facets or a polyhedron, returns a list of 3D segments representing all the edges of  $F$ . The result is not an "edge" object, and is drawn with the **g:Dpolyline3d** method.
- The function **facetvertices(F)**, where  $F$  is a list of facets or a polyhedron, returns the list of all vertices of  $F$  (3d points).

## 8) Methods and functions applying to facets or polyhedra

- The method **g:Isvisible(F)**, where  $F$  denotes a facet (list of at least 3 coplanar and non-aligned 3D points), returns true if facet  $F$  is visible (normal vector directed towards the observer). If  $A$ ,  $B$ , and  $C$  are the first three points of  $F$ , the normal vector is calculated by performing the vector product  $\vec{AB} \wedge \vec{AC}$ .
- The method **g:Classifyfacet(F)**, where  $F$  is a list of facets or a polyhedron, returns **two** lists of facets: the first is the list of visible facets, and the second, the list of invisible facets.
- The method **g:Sortfacet(F,backcull)**, where  $F$  is a list of facets, returns this list of facets sorted from furthest to closest to the observer. The optional argument *backcull* is a boolean that defaults to false; when it is true, non-visible facets are excluded from the result (only visible facets are then returned after being sorted). The calculation of a facet's distance is based on its center of gravity. The so-called "painter" technique consists of displaying the facets from furthest to closest, therefore in the order of the list returned by this function (the displayed result, however, is not always correct depending on the size and shape of the facets).
- The method **g:Sortpolyfacet(P,backcull)**, where  $P$  is a polyhedron, returns the list of facets of  $P$  (facets with 3D points) sorted from furthest to closest to the observer. The optional argument *backcull* is a boolean that defaults to false; when it is true, invisible facets are excluded from the result, as in the previous method. These two sorting methods are used by the methods for drawing polyhedrons or facets (*Dpoly*, *Dfacet*, and *Dmixfacet*).
- The method **g:Outline(P)**, where  $P$  is a polyhedron, returns the "outline" of  $P$  as a two-field table. One field, named *visible*, contains a 3D polygonal line representing the "edges" (segments) belonging to a single facet, the latter being visible, or to two facets, one visible and one hidden; the other field, named *hidden*, contains a 3D polygonal line representing the "edges" belonging to a single facet, the latter being hidden.
- The function **border(P)**, where  $P$  is a polyhedron or a list of facets, returns a 3D polygonal line corresponding to the edges belonging to a single facet of  $P$  (these edges are placed "end to end" to form a polygonal line).
- The function **getfacet(P,list)**, where  $P$  is a polyhedron, returns the list of facets of  $P$  (with 3D points) whose number appears in the table *list*. If the argument *list* is not specified, the list of all facets of  $P$  is returned (in this case, it is the same as **poly2facet(P)**).
- The function **facet2plane(L)**, where  $L$  is either a facet or a list of facets, returns either the plane containing the facet or the list of planes containing each of the facets of  $L$ . A plane is a table of the type  $\{A,u\}$  where  $A$  is a point on the plane and  $u$  is a normal vector to the plane (i.e., two 3D points).
- The function **reverse\_face\_orientation(F)** where  $F$  is either a facet, a list of facets, or a polyhedron, returns a result of the same nature as  $F$  but in which the order of the vertices of each facet has been reversed. This can be useful when the orientation of space has been changed.

```

1 \begin{luadraw}{name=sphere_octaedre}
2 require "luadraw_polyhedrons"
3 local g = graph3d:new{ window3d={-3,3,-3,3,-3,3}, size={10,10}}
4 local P = octahedron(Origin,M(0,0,3)) -- polyhedron defined in the luadraw_polyhedrons module
5 P = rotate3d(P,-10,{Origin,vecK}) -- rotate3d on a polyhedron returns a polyhedron

```

```

6 local V, H = g:Classifyfacet(P) -- V for visible facets, H for hidden
7 local S = map(function(p) return {proj3d(Origin,p),p[2]} end, facet2plane(V) )

16 end
17 g:Dfacet(V,{opacity=0.4, color="LightBlue"}) -- visible facets of the octahedron
18 g:Dcrossdots3d(S,nil,0.75) -- drawing of the projections on the faces
19 g:Dpolyline3d( {M(0,-3,3), M(0,0,3), M(-3,0,3)}, "gray")
20 g:Show()
21 \end{luadraw}

```

Figure 21: Sphere inscribed in an octahedron with the center projected onto the faces

## 9) Cutting a solid: cutpoly and cutfacet

- The function **cutpoly(P,plane,close)** cuts the polyhedron  $P$  with the plane  $plane$  (a table of type  $\{A,n\}$  where  $A$  is a point on the plane and  $n$  is a vector normal to the plane). The function returns three things: the part located in the half-space containing the vector  $n$  (in the form of a polyhedron), followed by the part located in the other half-space (still in the form of a polyhedron), followed by the section in the form of a facet oriented by  $-n$ . When the optional argument  $close$  is true, the section is added to both resulting polyhedra, which closes them (false by default).

Note: When the polyhedron  $P$  is not convex, the section result is not always correct.

```

1 \begin{luadraw}{name=cutpoly}
2 local g = graph3d:new(window3d={-3,3,-3,3,-3,3}, window={-4,4,-3,3},size={10,10})
3 local P = parallelep(M(-1,-1,-1),2*vecI,2*vecJ,2*vecK)
4 local A, B, C = M(0,-1,1), M(0,1,1), M(-1,-1,0)
5 local plane = {A, pt3d.prod(B-A,C-A)}
6 local P1 = cutpoly(P,plane)
7 local P2 = cutpoly(P,plane,true)
8 g:Lineoptions(nil,"Gold",8)
9 g:Dpoly( shift3d(P1,-2*vecJ), {color="Crimson",mode=mShadedHidden} )
10 g:Dpoly( shift3d(P2,2*vecJ), {color="Crimson",mode=mShadedHidden} )

```

```

11 g:Dlabel3d(
12     "close=false", M(2,-2,-1), {dir={vecJ,vecK}},
13     "close=true", M(2,2,-1), {}
14 )
15 g:Show()
16 \end{luadraw}

```

Figure 22: Cube cut by a plane (cutpoly), with *close=false* and with *close=true*

- The function **cutfacet(F,plane,close)**, where *F* is a facet, a list of facets, or a polyhedron, does the same thing as the previous function except that this function returns lists of facets and not polyhedra. This function was used in the contour line example in Figure 14.

## 10) Clipping Facets with a Convex Polyhedron: clip3d

The function **clip3d(S,P,exterior)** clips the solid *S* (a list of facets or a polyhedron) with the convex solid *P* (a list of facets or a polyhedron) and returns the resulting list of facets. The optional argument *exterior* is a boolean that defaults to false. In this case, the part of *S* that is interior to *P* is returned; otherwise, the part of *S* that is exterior to *P* is returned. **Note:** The result is not always satisfactory for the exterior part.

**Special case** : Clipping a list of facets *S* (or polyhedron) with the current 3D window can be done with this function as follows:

$$S = \text{clip3d}(S, \text{g:Box3d}())$$

Indeed, the **g:Box3d()** method returns the current 3D window as a parallelepiped.

```

1 \begin{luadraw}{name=clip3d}
2 local g = graph3d:new{window={-3,3,-3,3},size={10,10},viewdir=perspective("central")}
3 local S = sphere(Origin,3)
4 local C = parallelep(M(-2,-2,-2),4*vecI,4*vecJ,4*vecK)
5 local C1 = clip3d(S,C) -- sphere clipped by the cube
6 local C2 = clip3d(C,S) -- cube clipped by the sphere
7 local V = g:Classifyfacet(C2) -- visible facets of C2
8 g:Dfacet( concat(C1,C2), {color="Beige",mode=mShadedOnly,backcull=true} ) -- only visible faces
9 g:Dpolyline3d(V,true,"line width=0.8pt") -- outline of the visible faces of C2
10 local A, B, C, D = M(2,-2,-2), M(2,2,2), M(-2,2,-2), M(0,0,2) -- drawing black dots
11 g:Filloptions("full","black")
12 g:Dcircle3d( D,0.25,vecK); g:Dcircle3d( (2*A+B)/3,0.25,vecI)
13 g:Dcircle3d( (A+2*B)/3,0.25,vecI); g:Dcircle3d( (3*B+C)/4,0.25,vecJ)
14 g:Dcircle3d( (B+C)/2,0.25,vecJ); g:Dcircle3d( (B+3*C)/4,0.25,vecJ)
15 g:Show()
16 \end{luadraw}

```

Figure 23: Example with clip3d: constructing a die from a cube and a sphere

### 11) Clip a plane with a convex polyhedron: clipplane

The function **clipplane(plane,P)**, where the argument *plane* is a table of the form  $\{A,n\}$  representing the plane passing through  $A$  (3d point) and normal vector  $n$  (non-zero 3d point), and  $P$  is a convex polyhedron, returns the section of the polyhedron through the plane, if it exists, in the form of a facet (list of 3d points) oriented by  $n$ .

## VI The Dscene3d Method

### 1) The Principle, the Limitations

The major flaw of the **g:Dpoly**, **g:Dfacet**, and **g:Dmixfacet** methods is that they do not handle possible intersections between facets of different solids. Not to mention that sometimes, even for a simple convex polyhedron, the painter's algorithm does not always produce the correct result (because the facets are sorted only by their center of gravity). Furthermore, these methods only allow you to draw facets.

The principle of the **g:Dscene3d()** method is to classify the 3D objects to be drawn (facets, polygonal lines, points, labels, etc.) in a tree (which represents the scene). At each node of the tree, there is a 3D object, let's call it  $A$ , and two descendants. One of the descendants will contain the 3D objects that are in front of object  $A$  (i.e., closer to the observer than  $A$ ), and the other descendant will contain the 3D objects that are behind object  $A$  (i.e., further from the observer than  $A$ ).

In particular, to classify a facet  $B$  with respect to a facet  $A$  that is already in the tree, we proceed as follows: we split facet  $B$  with the plane containing facet  $A$ , which generally results in two "half" facets, one that will be in front of  $A$  (the one in the half-space "containing" the observer), and the other that will therefore be behind  $A$ .

This method is effective but has limitations because it can cause the number of facets in the tree to explode, thus increasing its size exponentially. This can make it prohibitive to use this method when there are many facets (long computation time<sup>4</sup>, excessively large tkz file size, excessively long drawing time per tikz). However, it is very effective when there are few facets, and therefore few facet intersections (convex objects with few facets). Furthermore, it is possible to draw below and above the 3D scene, i.e., before using the **g:Dscene3d** method, and after its use.

This method should therefore be reserved for very simple scenes. For complex 3D scenes, the vector format is not suitable, so it is better to turn to other tools like Povray, Blender, or WebGL.

<sup>4</sup>Lua is an interpreted language, so execution is generally longer than with a compiled language.

## 2) Construction of a 3D scene

The `g:Dscene3d(...)` method allows this construction. It takes as arguments the 3D objects that will constitute this scene one after the other. These 3D objects are themselves created using dedicated methods that will be detailed later. In the current version, these 3D objects can be:

- polyhedra,
- lists of facets (with point3d),
- 3D polygonal lines,
- 3D points,
- labels,
- axes,
- planes, lines,
- angles,
- circles, and arcs.

```

1 \begin{luadraw}{name=intersection_plans}
2 local g = graph3d:new{viewdir=perspective("central",-10,60), window={-5,6.5,-6.5,6},bg="gray", size={10,10}}
3 local P1 = planeEq(1,1,1,-2) -- plan d'équation  $x+y+z-2=0$ 
4 local P2 = {Origin, vecK-vecJ} -- plan passant par  $O$  et normal à  $(1,1,1)$ 
5 local D = interPP(P1,P2) -- droite d'intersection entre  $P1$  et  $P2$  ( $D = \{A,u\}$ )
6 local posD = D[1]+1.85*D[2] -- pour placer le label
7 Hiddenlines = true; Hiddenlinestyle = "dotted" -- affichage des lignes cachées en pointillées
8 g:Dscene3d(
9   g:addPlane(P1, {color="Crimson",edge=true,edgecolor="Pink",edgewidth=8}), -- ajout du plan  $P1$ 
10  g:addPlane(P2, {color="ForestGreen",edge=true,edgecolor="Pink",edgewidth=8}), -- ajout du plan  $P2$ 
11  g:addLine(D, {color="Navy",edgewidth=12}), -- ajout de la droite  $D$ 
12  g:addAxes(Origin, {arrows=1, color="Gold",width=8}), -- ajout des axes fléchés
13  g:addLabel( -- ajout de labels, ceux-ci auraient pu être ajoutés par dessus la scène
14    "$D=P_1 \cap P_2$",posD,{color="Navy"},
15    "$P_2$", M(3,0,0)+3.5*M(0,1,1)+0.2*vecI,{color="white",dir={vecI,vecJ+vecK}},
16    "$P_1$",M(2,0,0)+1.85*M(-1,-1,2)-1.5*M(-1,1,0), {dir={M(-1,1,0),M(-1,-1,2)}}
17  )
18 )
19 g:Show()
20 \end{luadraw}

```

Figure 24: First example with Dscene3d: intersection of two planes

### 3) Methods for adding an object to the 3D scene

These methods are to be used as arguments to the **g:Dscene3d(...)** method, as in the example above.

#### Adding facets: **g:addFacet** and **g:addPoly**

The **g:addFacet(list,options)** method, where *list* is a facet or a list of facets (with 3D points), allows you to add these facets to the scene.

The **g:addPoly(list,options)** method allows you to add the polyhedron *P* to the scene.

In both cases, the optional *options* argument is a 12-field table. These options (with their default values) are:

- **color="white"**: Sets the fill color of the facets. This color will be shaded depending on their inclination. By default, the edges of the facets are not drawn (only the fill).
- **usepalette** (*nil* by default), this option allows you to specify a color palette for painting the facets as well as a calculation mode, the syntax is: *usepalette = {palette,mode}*, where *palette* designates a table of colors which are themselves tables of the form  $\{r,g,b\}$  where *r*, *g* and *b* are numbers between 0 and 1, and *mode* which is a string which can be either "x", or "y", or "z". In the first case for example, the facets at the center of gravity of minimum abscissa have the first color of the palette, the facets at the center of gravity of maximum abscissa have the last color of the palette, for the others, the color is calculated according to the abscissa of the center of gravity by linear interpolation.
- **opacity=1**: Number between 0 and 1 to define the opacity of the facets (1 means no transparency).
- **backcull=false**: Boolean indicating whether invisible facets should be excluded from the scene. By default, they are present.
- **clip=false**: Boolean indicating whether the facets should be clipped by the 3D window.
- **contrast=1**: Numerical value to increase or decrease the color contrast between the facets. With a value of 0, all facets have the same color.
- **twoside=true**: Boolean indicating whether the inner and outer sides of the facets are distinguished. The color of the inner side is slightly lighter than that of the outer side.
- **edge=false**: Boolean indicating whether edges should be added to the scene.

- `edgecolor=`: Indicates the color of the edges when they are drawn; this is the current color by default.
- `edgewidth=`: Indicates the line thickness (in tenths of a point) of the edges; this is the current thickness by default.
- `hidden=Hiddenlines`: Boolean indicating whether hidden edges should be drawn. *Hiddenlines* is a global variable that defaults to false.
- `hiddenstyle=Hiddenlinestyle`: String defining the line style of the hidden edges. *Hiddenlinestyle* is a global variable that defaults to "dotted."
- `matrix=ID3d`: 3D facet transformation matrix, by default this is the 3D identity matrix, i.e. the table  $\{M(0,0,0), \text{vecI}, \text{vecJ}, \text{vecK}\}$ .

### Adding a plane: `g:addPlane` and `g:addPlaneEq`

The `g:addPlane(P,options)` method adds the plane  $P$  to the 3D scene. This plane is defined as a table  $\{A,u\}$  where  $A$  is a point on the plane (a 3D point) and  $u$  is a normal vector to the plane (a non-zero 3D point). This function determines the intersection between this plane and the parallelepiped given by the *window3d* argument (itself defined when the graph is created), which results in a facet, which is added to the scene. This method uses `g:addFacet`.

The method `g:addPlaneEq(coef,options)`, where *coef* is a table consisting of four real numbers  $\{a,b,c,d\}$ , allows you to add the plane with the equation  $ax + by + cz + d = 0$  to the scene (this method uses the previous one).

In both cases, the optional argument *options* is a table with 12 fields. These options are those of the `g:addFacet` method, plus the option `scale=1`: this number is a homothety ratio. The homothety ratio is applied to the facet with the center of gravity of the facet and the ratio *scale*. This allows you to adjust the size of the plane in its representation.

### Add a polygonal line: `g:addPolyline`

The method `g:addPolyline(L,options)`, where  $L$  is a list of 3D points, or a list of lists of 3D points, adds  $L$  to the scene. The optional argument *options* is a 10-field table. These options (with their default values) are:

- `style="solid"`: to set the line style; this is the current style by default.
- `color=`: line color; this is the current color by default.
- `close=false`: indicates whether the line  $L$  (or each component of  $L$ ) should be closed.
- `clip=false`: Indicates whether the line  $L$  (or each component of  $L$ ) should be clipped by the 3D window.
- `width=`: Line thickness in tenths of a point; this is the current thickness by default.
- `opacity=1`: Opacity of the line drawing (1 means no transparency).
- `hidden=Hiddenlines`: Boolean indicating whether the hidden parts of the line should be represented. *Hiddenlines* is a global variable that defaults to false.
- `hiddenstyle=Hiddenlinestyle`: String defining the line style of the hidden parts. *Hiddenlinestyle* is a global variable that defaults to "dotted."
- `arrows=0`: This option can be 0 (no arrow added to the line), 1 (an arrow added at the end of the line), or 2 (an arrow at the beginning and end of the line). The arrows are small cones.
- `arrowscale=1`: Allows you to reduce or increase the size of the arrows.
- `matrix=ID3d`: 3D transformation matrix (of the line). By default, this is the 3D identity matrix, i.e., the table  $\{M(0,0,0), \text{vecI}, \text{vecJ}, \text{vecK}\}$ .

### Add Axes: `g:addAxes`

The `g:addAxes(O,options)` method adds the axes  $(O, \text{vecI})$ ,  $(O, \text{vecJ})$ , and  $(O, \text{vecK})$  to the 3D scene, where the argument  $O$  is a 3D point. The options are those of the `g:addPolyline` method, plus the `legend=true` option, which automatically adds the name of each axis ( $x$ ,  $y$ , and  $z$ ) to the endpoint. These axes are not graduated.

**Add a line: g:addLine**

The **g:addLine(d,options)** method adds the line  $d$  to the scene. This line  $d$  is a table of the form  $\{A,u\}$  where  $A$  is a point on the line (3D point) and  $u$  is a direction vector (non-zero 3D point). The optional argument *options* is a 10-field table. These options are those of the **g:addPolyline** method, plus the **scale=1** option: this number is a homothety ratio. The homothety ratio is applied to the facet, with the center being the midpoint of the segment representing the line, and the ratio *scale*. This allows you to adjust the size of the segment in its representation. This segment is the line clipped by the polyhedron given by the *window3d* argument (itself defined when the graph is created), which results in a segment (possibly empty).

**Adding a "right" angle: g:addAngle**

The **g:addAngle(B,A,C,r,options)** method allows you to add the angle  $\widehat{BAC}$  in the form of a parallelogram with side  $r$  ( $r$  is 0.25 by default). Only two sides are represented. The arguments  $B$ ,  $A$ , and  $C$  are 3D points. The options are those of the **g:addPolyline** method.

**Add a circular arc: g:addArc**

The **g:addArc(B,A,C,r,direction,normal,options)** method adds the arc of a circle centered at  $A$  (3D point), with radius  $r$ , extending from  $B$  to  $C$  (3D points) in the direct direction if *direction* is 1 (indirect otherwise). The arc is drawn in the plane passing through  $A$  and orthogonal to the *normal* vector (non-zero 3D point); this same vector orients the plane. The options are those of the **g:addPolyline** method.

**Add a circle: g:addCircle**

The **g:addCircle(A,r,normal,options)** method adds the circle with center  $A$  (3D point) and radius  $r$  in the plane passing through  $A$  and orthogonal to the *normal* vector (non-zero 3D point). The options are those of the **g:addPolyline** method.

```

1  \begin{luadraw}{name=cylindres_imbriques}

32 g:Dpolyline3d( {A,B}, "<->" ); g:Dlabel3d("$2\\$,cm", (A+B)/2, {pos="W"})
33 g:Show()
34 \end{luadraw}

```

Figure 25: Solid cylinder immersed in water

**Notes :**

- The **g:ScreenX()** method returns the space vector (3D point) corresponding to the vector with affix  $l$  in the screen plane, and the **g:ScreenY()** method returns the space vector (3D point) corresponding to the vector with affix  $i$  in the screen plane.
- For the small cylinder (C3), we use the **backcull=true** option to reduce the number of facets; however, we do not do this for the other two cylinders (C1 and C2) because they are transparent.

**Adding points: g:addDots**

The **g:addDots(dots,options)** method allows you to add 3D points to the scene. The argument *dots* is either a 3D point or a list of 3D points. The optional argument *options* is a four-field table. These options are:

- **style="ball"**: String defining the dot style. These are all 2D point styles, plus the "ball" (sphere) style, which is the default.
- **color="black"**: String defining the dot color.
- **scale=1**: Number allowing you to adjust the size of the points.
- **matrix=ID3d**: 3D transformation matrix. By default, this is the 3D identity matrix, i.e., the table  $\{M(0,0,0), \text{vecI}, \text{vecJ}, \text{vecK}\}$ .

**Adding Labels: g:addLabels**

The **g:addLabel(text1, anchor1, options1, text2, anchor2, options2, ...)** method allows you to add the labels *text1*, *text2*, etc. The (required) arguments *anchor1*, *anchor2*, etc., are 3D points representing the anchor points of the labels. The (required) arguments *options1*, *options2*, etc., are 7-field tables. These options are:

- **color**: String defining the label color, initialized to the current label color.
- **pos**: A string defining the position of the label relative to the anchor point (as in 2d: "N", "NW", "W", ...), initialized to the current style of the labels.

- `dist=0`: Expresses the distance between the label and its anchor point (in the screen plane).
- `size`: String defining the label size, initialized to the current label size.
- `dir={}`: Table defining the writing direction in space (usual direction by default). In general,  $dir=\{dirX, dirY, dep\}$ , and the three values  $dirX$ ,  $dirY$ , and  $dep$  are three 3D points representing three vectors: the first two indicate the writing direction, the third a displacement (translation) of the label relative to the anchor point.
- `showdot=false`: Boolean indicating whether a (2D) point should be drawn at the anchor point.
- `matrix=ID3d`: 3D transformation matrix; by default, this is the 3D identity matrix, i.e., the table  $\{M(0,0,0), vecI, vecJ, vecK\}$ .

24 \end{luadraw}

```

Figure 26: Construction of an icosahedron

### Adding dividing walls: `g:addWall`

Dividing walls are 3D objects that are inserted first into the scene tree. These objects are not drawn (therefore invisible); their role is to partition the space because a facet on one side of a dividing wall cannot be cut by the plane of a facet on the

other side of the wall. This allows, in some cases, to significantly reduce the number of facet (or polygonal line) cuts during scene construction. A dividing wall can be an entire plane (i.e., a table of two 3D points of the form  $\{A,n\}$ , i.e., a point and a normal vector), or just a facet.

The syntax is: **g:addWall(C,options)** where *C* is either a plane, a list of planes, a facet, or a list of facets. The *options* argument is a table. The only available option is

- **matrix=ID3d**: 3D transformation matrix. By default, this is the 3D identity matrix, i.e., the table  $\{M(0,0,0),\text{vecI},\text{vecJ},\text{vecK}\}$ .

In the following example, the two dividing walls have been drawn for visualization, but they are normally invisible:

```

1 \begin{luadraw}{name=addWall}
2 local g = graph3d:new{size={10,10},window={-8,8,-4,8}, margin={0,0,0,0}}
3 local C = cylinder(M(0,0,-1),5*vecK,2)
4 g:Dscene3d(
5   g:addWall( { {Origin,vecI}, {Origin,vecJ} } ),
6   g:addPlane({Origin,vecI}, {color="Pink",opacity=0.3,scale=1.125,edge=true}), -- to show the first wall
7   g:addPlane({Origin,vecJ}, {color="Pink",opacity=0.3,scale=1.125,edge=true}), -- to show the second wall
8   g:addPoly( shift3d(C,M(-3,-3,1)), {color="Cyan"} ),
9   g:addPoly( shift3d(C,M(-3,3,0.5)), {color="ForestGreen"} ),
10  g:addPoly( shift3d(C,M(3,-3,-0.5)), {color="Crimson"} )
11 )
12 g:Show()
13 \end{luadraw}

```

Figure 27: Example with addWall (the two transparent pink facets are normally invisible)

#### Notes on this example :

- with the two dividing walls, there are no cut facets, and the scene contains exactly 111 (37 per cylinder).
- without the dividing walls, there are 117 (useless) facet cuts, bringing their number to 228 in the scene.
- with the two dividing walls, and the **backcull=true** option for each cylinder, there are no cut facets, and the scene contains only 57.

Here is another, much more convincing example where the use of dividing walls is essential to have a drawing of reasonable size. It involves obtaining a lemniscate as the intersection of a torus with a certain plane. Since the torus is non-convex, the number of unnecessary facet cuts can be very high.

```

1 \begin{luadraw}{name=torus}
2 local g = graph3d:new{size={10,10}, margin={0,0,0,0}}
3 local cos, sin, pi = math.cos, math.sin, math.pi
4 local R, r = 2.5, 1
5 local x0 = R-r
6 local f = function(t) return M(0,R+r*cos(t),r*sin(t)) end

```

```

7 local plan = {M(x0,0,0),-vecI} -- plane whose section with the torus gives the lemniscate
8 local C, wall = rotcurve(f,-pi,pi,{Origin,vecK},360,0,{grid={25,37},addwall=2})
9 local C1 = cutfacet(C,plan) -- part of the torus in the half-space containing -vecI
10 g:Dscene3d(
11   g:addWall(plan), g:addWall(wall), -- addition of partition walls
12   g:addFacet( C1, {color="Crimson", backcull=false}),
13   g:addPlane(plan, {color="Pink",opacity=0.4,edge=true}), -- sectional plan
14   g:addAxes( Origin, {arrows=1})
15 )
16 -- Cartesian equation of the torus :  $(x^2+y^2+z^2+R^2-r^2)^2-4*R^2*(x^2+y^2) = 0$ 
17 -- the lemniscate therefore has the equation  $(x^2+y^2+z^2+R^2-r^2)^2-4*R^2*(x^2+y^2)=0$  (implicit curve)
18 local h = function(y,z) return (x0^2+y^2+z^2+R^2-r^2)^2-4*R^2*(x0^2+y^2) end
19 local I = implicit(h,-4,4,-3,3,{50,50}) -- 2d polygonal line (list of lists of complex numbers)
20 local lemniscate = map(function(z) return M(x0,z.re,z.im) end, I[1]) -- conversion to 3d coordinates
21 g:Dpolyline3d(lemniscate,"Navy,line width=1.2pt")
22 g:Show()
23 \end{luadraw}

```

Figure 28: Torus and lemniscate

**Notes on this example :**

- With the dividing walls, we have 30 facets that are cut and a tkz file of approximately 140 KB.
- Without the dividing walls, we have 2068 facet cuts (!) and a tkz file of approximately 550 KB.
- We could have used the cut section returned by the *cutfacet* function, but the result is not very satisfactory (this is because the torus is non-convex).
- If we hadn't wanted the axes passing through the torus and the cutting plane, we could have drawn the drawing with the **g:Dfacet** method, replacing the *g:Dscene3d(...)* instruction with:

```

1 g:Dfacet(C1, {mode=mShadedOnly,color="Crimson"} )
2 g:Dfacet( g:Plane2facet(plan,0.75), {color="Pink",opacity=0.4})

```

We get exactly the same thing but without the axes (and without facet cutting, of course).

**To conclude this section :** we use the **g:Dscene3d()** method when it is not possible to do otherwise, for example when there are intersections (few) that cannot be handled "by hand". But this isn't the case for all intersections! In the following

example, we represent a section of a sphere using a plane, but without using the **g:Dscene3d()** method, as this would require drawing a faceted sphere, which isn't very attractive. The trick here is to draw the sphere using the **g:Dsphere()** method, then draw a previously perforated facet over the plane, the hole corresponding to the outline (3D path) of the part of the sphere located above the plane:

```

1  \begin{luadraw}{name=section_sphere}
2  local g = graph3d:new{ window3d={-4,4,-4,4,-4,4}, window={-5.5,5.5,-4,5}, viewdir={30,75}, size={10,10}}
3  local O, R = Origin, 2.5 -- center and radius
4  local S, P = sphere(O,R), {M(0,0,1.5),vecK+vecJ/2} -- the sphere and the section plane
5  local w, n = pt3d.normalize(P[2]), g.Normal -- unit vectors normal to P for w and to the screen for n
6  local I, r = interPS(P,{O,R}) -- center and radius of the small circle (intersection between the plane and the sphere)
7  local C = g:Intersection3d(S,P) -- It is a list of edges
8  local N = I-O
9  local J = I+r*pt3d.normalize(vecJ-vecK/2) -- a point on the small circle
10 local a = R/pt3d.abs(N)
11 local A, B = O+a*N, O-a*N -- points of intersection of the axis (O,I) with the sphere
12 local c1, alpha = Orange, 0.4
13 local coul = {c1[1]*alpha, c1[2]*alpha,c1[3]*alpha} -- to simulate transparency
14 g:Dhline( g:Proj3d({B,-N})) -- half-line (point B is not visible)
15 g:Dsphere(O,R,{mode=mBorder,color="orange"})
16 g:Dline3d(A,B,"dotted") -- dotted line (A,B)
17 g:Dedges(C, {hidden=true,hiddenstyle="dashed"}) -- drawing of the intersection
18 g:Dpolyline3d({I,J,O},"dashed")
19 g:Dangle3d(O,I,J) -- right angle
20 g:Dcrossdots3d({{B,N},{I,N},{O,N}},rgb(coul),0.75) -- points in the sphere
21 g:Dlabel3d("$O$", O, {pos="NW"})
22 local L = C.visible[1] -- visible part of the intersection (arc of a circle)
23 A1 = L[1]; A2 = L[#L] -- ends of L
24 local F = g:Plane2facet(P) -- plan converted to facet
25 -- hole plane as 3d path, the hole is the outline of the part of the sphere above the plane
26 insert(F,{"l","c1",A1,"m",I,A2,r,-1,w,"ca",Origin,A1,R,-1,n,"ca"})
27 g:Dpath3d( F,"fill=Beige,fill opacity=0.6") -- drawing of the perforated plan
28 g:Dhline( g:Proj3d({A,N})) -- half-line, upper part of the axis (AB)
29 g:Dcrossdots3d({A,N},"black",0.75); g:Dballdots3d(J,"black",0.75)
30 g:Dlabel3d("$A$", A, {pos="NW"}, "$I$", I, {}, "$B$", B, {pos="E"}, "$J$", J, {pos="S"})
31 g:Show()
32 \end{luadraw}

```

Figure 29: Section of a sphere without Dscene3d()

## VII Geometric Constructions

This section groups together functions that construct geometric figures without dedicated graphics methods.

## 1) Circumscribed circle, incircle: `circumcircle3d()`, `incircle3d()`

- The function **`circumcircle3d(A,B,C)`**, where  $A$ ,  $B$ , and  $C$  are three non-aligned 3D points, returns the circumcircle of the triangle formed by these three points, in the form of a sequence:  $A, R, n$ , where  $A$  is the center of the circle,  $R$  its radius, and  $n$  a normal vector to the plane of the circle.
- The function **`incircle3d(A,B,C)`**, where  $A$ ,  $B$ , and  $C$  are three non-aligned 3D points, returns the circle inscribed in the triangle formed by these three points, as a sequence:  $A, R, n$ , where  $A$  is the center of the circle,  $R$  its radius, and  $n$  a normal vector to the plane of the circle.

## 2) Convex Hull: `cvx_hull3d()`

The function **`cvx_hull3d(L)`**, where  $L$  is a list of **distinct** 3D points, calculates and returns the convex hull of  $L$  as a list of facets.

```

1 \begin{luadraw}{name=cvx_hull3d}
2 local g = graph3d:new{window={-2,4,-6,1},bbox=false,size={10,10}}
3 local L = {Origin, 4*vecI, M(4,4,0), 4*vecJ}
4 insert(L, shift3d(L,-3*vecK))
5 insert(L, {M(2,1,2), M(2,3,2)})
6 local V = cvx_hull3d(L)
7 local P = facet2poly(V)
8 g:Dpoly(P, {color="cyan",mode=mShadedHidden})
9 g:Show()
10 \end{luadraw}

```

Figure 30: Using `cvx_hull3d()`

**Special case** : when all points of  $L$  are in the same plane, we can use the function **`cvx_hull3dcoplanar(L,n)`** where  $n$  is a vector orthogonal to the plane. This function returns a facet (list of 3d points).

## 3) Planes: `plane()`, `planeEq()`, `orthoframe()`, `plane2ABC()`

A plane in space is a table of the form  $\{A, n\}$  where  $A$  is a point in the plane (3d point) and  $n$  is a normal vector to the plane (non-zero 3d point).

- The function **`plane(A,B,C)`** returns the plane passing through the three 3d points  $A$ ,  $B$ , and  $C$  (if they are not aligned, otherwise the result is *nil*).
- The function **`planeEq(a,b,c,d)`** returns the plane whose Cartesian equation is  $ax + by + cz + d = 0$  (if the coefficients  $a$ ,  $b$ , and  $c$  are not all zero, otherwise the result is *nil*).

- The function **plane2ABC(P)**, where  $P = \{A, n\}$  denotes a plane, returns a sequence of three 3d points  $A, B, C$ , belonging to the plane, and such that  $(A, \vec{AB}, \vec{AC})$  is a direct orthonormal frame of this plane.
- The function **orthoframe(P)**, where  $P = \{A, n\}$  denotes a plane, returns a sequence of three 3d points  $A, u, v$ , such that  $(A, u, v)$  is a direct orthonormal frame of this plane.

```

1 \begin{luadraw}{name=plans}

```

Figure 31: Faces of a cube with holes in it and a regular hexagon

#### 4) Circumscribed Sphere, Inscribed Sphere: **circumsphere()**, **insphere()**

- The function **circumsphere(A,B,C,D)**, where  $A, B, C$ , and  $D$  are four non-coplanar 3d points, returns the sphere circumscribed within the tetrahedron formed by these four points, as a sequence:  $A, R$ , where  $A$  is the center of the sphere, and  $R$  its radius.
- The function **insphere(A,B,C,D)**, where  $A, B, C$ , and  $D$  are four non-coplanar 3d points, returns the sphere inscribed within the tetrahedron formed by these four points, as a sequence:  $A, R$ , where  $A$  is the center of the sphere, and  $R$  its radius.

### 5) Fixed-length tetrahedron: `tetra_len()`

The function `tetra_len(ab,ac,ad,bc,bd,cd)` calculates the vertices  $A, B, C, D$  of a tetrahedron whose edge lengths are given, i.e., such that  $AB = ab$ ,  $AC = ac$ ,  $AD = ad$ ,  $BC = bc$ ,  $BD = bd$ , and  $CD = cd$ . The function returns the sequence of four points  $A, B, C, D$ . Vertex  $A$  is always the point  $M(0,0,0)$  (*Origin*) and vertex  $B$  is always the point  $ab \cdot \text{vecI}$  and vertex  $C$  in the  $xOy$  plane. The tetrahedron as a polyhedron can then be constructed with the function `tetra(A,B-A,C-A,D-A)`.

```

1 \begin{luadraw}{name=tetra_len}

14 g:Dspherical()
15 g:Ddots3d({A,B,C,D})
16 g:Dlabel3d("$A$", A, {pos="S"}, "$B$", B, {pos="SW"}, "$C$", C, {pos="SE"}, "$D$", D, {pos="N"})
17 g:Show()
18 \end{luadraw}

```

Figure 32: A tetrahedron with fixed edge lengths

### 6) Triangles: `sss_triangle3d()`, `sas_triangle3d()`, `asa_triangle3d()`

These functions are the 3D version of the `sss_triangle()`, `sas_triangle()`, and `asa_triangle()` functions already described.

- The function `sss_triangle3d(ab,bc,ca)`, where  $ab$ ,  $bc$ , and  $ca$  are three lengths, computes and returns a list of three 3D points  $\{A, B, C\}$  forming the vertices of a direct triangle in the  $xOy$  plane, whose side lengths are the arguments, i.e.,  $AB = ab$ ,  $BC = bc$ , and  $CA = ca$ , when possible. Vertex  $A$  is always point  $M(0,0,0)$  (*Origin*) and vertex  $B$  is always point  $ab \cdot \text{vecI}$ . This triangle can be drawn with the method `g:Dpolyline3d`.
- The function `sas_triangle3d(ab,alpha,ca)` where  $ab$  and  $ca$  are two lengths,  $\alpha$  an angle in degrees, computes and returns a list of three 3d points  $\{A, B, C\}$  forming the vertices of a triangle in the plane  $xOy$  such that  $AB = ab$ ,

$CA = ca$ , and such that the angle  $(\vec{AB}, \vec{AC})$  has measure *alpha*, when possible. Vertex *A* is always point  $M(0,0,0)$  (*Origin*) and vertex *B* is always point  $ab*vecI$ . This triangle can be drawn with the method **g:Dpolyline3d**.

- The function **asa\_triangle3d(alpha,ab,beta)** where *ab* is a length, *alpha* and *beta* are two angles in degrees, computes and returns a list of three 3d points  $\{A, B, C\}$  forming the vertices of a triangle in the  $xOy$  plane such that  $AB = ab$ , such that angle  $(\vec{AB}, \vec{AC})$  has measure *alpha*, and such that angle  $(\vec{BA}, \vec{BC})$  has measure *beta*, when possible. Vertex *A* is always point  $M(0,0,0)$  (*Origin*) and vertex *B* is always point  $ab*vecI$ . This triangle can be drawn with the **g:Dpolyline3d** method.

## VIII Matrix Calculus Transformations and Some Mathematical Functions

### 1) 3D Transformations

In the following functions:

- the argument *L* is either a 3D point, a polyhedron, a list of 3D points (facet), or a list of lists of 3D points (facet list),
- a line *d* is a list of two 3D points  $\{A, u\}$ : a point on the line (*A*) and a direction vector (*u*),
- a plane *P* is a list of two 3D points  $\{A, n\}$ : a point on the plane (*A*) and a normal vector to the plane (*n*).

The returned result is of the same type as *L*.

#### Apply a transformation function: **ftransform3d**

The function **ftransform3d(L,f)** returns the image of *L* by the function *f*; this must be a function from  $\mathbf{R}^3$  to  $\mathbf{R}^3$ .

#### Projections: **proj3d**, **proj3dO**, **dproj3d**

- The function **proj3d(L,P)** returns the image of *L* by the orthogonal projection onto the plane *P*.
- The function **proj3dO(L,P,v)** returns the image of *L* by the projection onto the plane *P* parallel to the direction of the vector *v* (non-zero 3d point).
- The function **dproj3d(L,d)** returns the image of *L* by the projection onto the line *d*.

#### Projections onto axes or planes related to axes

- The function **pxy(L,z0)** returns the image of *L* by the orthogonal projection onto the  $z = z0$  plane (by default  $z0 = 0$ ).
- The function **pyz(L,x0)** returns the image of *L* by the orthogonal projection onto the  $x = x0$  plane (by default  $x0 = 0$ ).
- The function **pxz(L,y0)** returns the image of *L* by the orthogonal projection onto the  $y = y0$  plane (by default  $y0 = 0$ ).
- The function **px(L)** returns the image of *L* by the orthogonal projection onto the *Ox* axis.
- The function **py(L)** returns the image of *L* by the orthogonal projection onto the *Oy* axis.
- The function **pz(L)** returns the image of *L* by the orthogonal projection onto the *Oz* axis.

#### Symmetries: **sym3d**, **sym3dO**, **dsym3d**, **psym3d**

- The function **sym3d(L,P)** returns the image of *L* by the orthogonal symmetry about the *P* plane.
- The function **sym3dO(L,P,v)** returns the image of *L* by the symmetry about the *P* plane and parallel to the direction of the *v* vector (non-zero 3d point).
- The function **dsym3d(L,d)** returns the image of *L* by the orthogonal symmetry with respect to the line *d*.
- The function **psym3d(L,point)** returns the image of *L* by the symmetry with respect to *point* (3d point).

**Rotation: rotate3d, rotateaxe3d**

- The function **rotate3d(L,angle,d)** returns the image of  $L$  rotated along axis  $d$  (oriented by the direction vector, which is  $d[2]$ ), and by  $angle$  degrees.
- The function **rotateaxe3d(L,v1,v2,center)** returns the image of  $L$  rotated along axis passing through the 3d point  $center$ , which transforms the vector  $v1$  into the vector  $v2$ . These vectors are normalized by the function. The argument  $center$  is optional and defaults to the point *Origin*.

**Scaling: scale3d**

The function **scale3d(L,k,center)** returns the image of  $L$  by the scaling with center at the 3D point  $center$ , and ratio  $k$ . The argument  $center$  is optional and is  $M(0,0,0)$  by default (origin).

**Inversion: inv3d**

The function **inv3d(L,radius,center)** returns the image of  $L$  by the inversion with respect to the sphere with center  $center$ , and radius  $radius$ . The argument  $center$  is optional and is  $M(0,0,0)$  by default (origin).

**Stereography: projstereo and inv\_projstereo**

Function **projstereo(L,S,N,h)**: the argument  $L$  denotes a 3D point or a list of 3D points or a list of lists of 3D points, all belonging to the sphere  $S$ , where  $S=\{C,r\}$  ( $C$  is the center of the sphere, and  $r$  the radius). The argument  $N$  denotes a point on the sphere that will be the pole of the projection. The argument  $h$  is a real number that defines the projection plane. This plane is perpendicular to the axis  $(CN)$ , and passes through the point  $I = C + h \frac{\vec{CN}}{CN}$  (with  $h = 0$  it is the equatorial plane, with  $h = -r$  it is the plane tangent to the sphere at the opposite pole). The function returns the image of  $L$  by the stereographic projection with respect to the sphere  $S$  with  $N$  as pole, and on the plane  $\{I,N-C\}$ .

Inverse function **inv\_projstereo(L,S,N)**:  $S=\{C,r\}$  is the sphere with center  $C$  and radius  $r$ ,  $N$  is a point on the sphere  $S$  (pole), and  $L$  is a 3D point or a list of 3D points or a list of lists of 3D points all belonging to the same plane orthogonal to the  $(CN)$  axis. The function returns the image of  $L$  by the inverse of the stereographic projection with respect to  $S$  and with pole  $N$ .

**Translation: shift3d**

The function **shift3d(L,v)** returns the image of  $L$  by the translation of vector  $v$  (3D point).

**2) Matrix Calculus**

If  $f$  is an affine mapping of the space  $\mathbf{R}^3$ , we will call the list (table) of  $f$  a matrix:

```
1 { f(Origin), Lf(vecI), Lf(vecJ), Lf(vecK) }
```

where  $Lf$  denotes the linear part of  $f$  (we have  $Lf(vecI) = f(vecI) - f(Origin)$ , etc.). The identity matrix is denoted  $ID3d$  in the *luadraw* package; it simply corresponds to the list `{Origin,vecI,vecJ,vecK}` .

**applymatrix3d and applyLmatrix3d**

- The function **applymatrix3d(A,M)** applies the matrix  $M$  to the 3d point  $A$  and returns the result (which is equivalent to calculating  $f(A)$  if  $M$  is the matrix of  $f$ ). If  $A$  is not a 3d point, the function returns  $A$ .
- The function **applyLmatrix3d(A,M)** applies the linear part of the matrix  $M$  to the 3d point  $A$  and returns the result (which is equivalent to calculating  $Lf(A)$  if  $M$  is the matrix of  $f$ ). If  $A$  is not a 3d point, the function returns  $A$ .

**composematrix3d**

The function **composematrix3d(M1,M2)** performs the matrix product  $M1 \times M2$  and returns the result.

**invmatrix3d**

The function **invmatrix3d(M)** calculates and returns the inverse of the matrix  $M$  when possible.

**matrix3dof**

The function **matrix3dof(f)** calculates and returns the matrix of  $f$  (which must be an affine mapping of the space  $\mathbf{R}^3$ ).

**mtransform3d and mLtransform3d**

- The function **mtransform3d(L,M)** applies the matrix  $M$  to the list  $L$  and returns the result.  $L$  must be a list of 3D points (a facet) or a list of lists of 3D points (a list of facets).
- The function **mLtransform3d(L,M)** applies the linear part of the matrix  $M$  to the list  $L$  and returns the result.  $L$  must be a list of 3D points (a facet) or a list of lists of 3D points (a list of facets).

**3) Matrix associated with the 3D graph**

When creating a graph in the *luadraw* environment, for example:

```
1 local g = graph3d:new{size={10,10}}
```

The created  $g$  object has a 3D transformation matrix that is initially the identity. All graphics methods automatically apply the graph's 3D transformation matrix. One caveat, however: the *Dcylinder*, *Dcone*, and *Dsphere* methods only yield the correct result with the transformation matrix equal to the identity. To manipulate this matrix, the following methods are available.

**g:Composematrix3d()**

The **g:Composematrix3d(M)** method multiplies the 3d matrix of the graph  $g$  by the matrix  $M$  (with  $M$  on the right), and the result is assigned to the graph's 3d matrix. The argument  $M$  must therefore be a 3d matrix.

**g:Det3d()**

The **g:Det3d()** method returns 1 when the 3d transformation matrix has a positive determinant, and  $-1$  otherwise. This information is useful when we need to know whether the orientation of space has been changed or not.

**g:IDmatrix3d()**

The **g:IDmatrix3d()** method reassigns the identity to the 3d matrix of the graph  $g$ .

**g:Mtransform3d()**

The **g:Mtransform3d(L)** method applies the 3d graph matrix of  $g$  to  $L$  and returns the result. The argument  $L$  must be a list of 3d points (a facet) or a list of lists of 3d points (a list of facets).

**g:MLtransform3d()**

The **g:MLtransform3d(L)** method applies the linear part of the 3d matrix of the graph  $g$  to  $L$  and returns the result. The argument  $L$  must be a list of 3D points (a facet) or a list of lists of 3D points (a list of facets).

**g:Rotate3d()**

The method **g:Rotate3d(angle,axis)** modifies the 3D transformation matrix of the graph  $g$  by composing it with the rotation matrix of angle  $angle$  (in degrees) and axis  $axis$ .

**g:Scale3d()**

The method **g:Scale3d(factor, center)** modifies the 3D transformation matrix of the graph  $g$  by composing it with the homothety matrix of ratio  $factor$  and center  $center$ . The argument  $center$  is a 3D point that defaults to *Origin*.

**g:Setmatrix3d()**

The **g:Setmatrix3d(M)** method assigns the matrix  $M$  to the 3D transformation matrix of the graph  $g$ .

**g:Shift3d()**

The **g:Shift3d(v)** method modifies the 3D transformation matrix of the graph  $g$  by composing it with the translation matrix of vector  $v$ , which must be a 3D point.

**4) Additional Mathematical Functions****clippolyline3d()**

The function **clippolyline3d(L, poly, exterior, close)** clips the 3D polygonal line  $L$  to the **convex** polyhedron  $poly$ . If the optional argument *exterior* is true, then the part outside the polyhedron is returned (false by default). If the optional argument *close* is true, then the polygonal line is closed (false by default).  $L$  is a list of 3D points or a list of lists of 3D points.

**Note:** The result is not always satisfactory for the exterior part.

**Special case** : Clipping a 3D polygonal line  $L$  with the current 3D window can be done with this function as follows:

$$L = \text{clippolyline3d}(L, \text{g:Box3d}())$$

Indeed, the **g:Box3d()** method returns the current 3D window as a parallelepiped.

**clipline3d()**

The function **clipline3d(line, poly)** clips the line  $line$  with the **convex** polyhedron  $poly$ ; the function returns the part of the line inside the polyhedron. The argument  $line$  is a table of the form  $\{A, u\}$  where  $A$  is a point on the line and  $u$  is a direction vector (two 3D points).

**Special case** : Clipping a line  $d$  with the current 3D window can be done with this function as follows:

$$d = \text{clipline3d}(d, \text{g:Box3d}())$$

Indeed, the **g:Box3d()** method returns the current 3D window as a parallelepiped ( $d$  then becomes a segment).

**cutpolyline3d()**

The function **cutpolyline3d(L, plane, close)** intersects the 3D polygonal line  $L$  with the plane  $plane$ . If the optional argument *close* is true, then the line is closed (false by default).  $L$  is a list of 3D points or a list of lists of 3D points,  $plane$  is a table of the form  $\{A, n\}$  where  $A$  is a point in the plane and  $n$  is a normal vector (two 3D points).

The function returns three things:

- the part of  $L$  that is in the half-space containing the vector  $n$ ,
- followed by the part of  $L$  that is in the other half-space,
- followed by the list of intersection points.

**getbounds3d()**

The function **getbounds3d(L)** returns the bounds  $xmin, xmax, ymin, ymax, zmin, zmax$  of the 3D polygonal line  $L$  (list of 3D points or a list of lists of 3D points).

**interDP()**

The function **interDP(d, P)** calculates and returns (if it exists) the intersection between line  $d$  and plane  $P$ .

**interPP()**

The function **interPP(P1,P2)** calculates and returns (if it exists) the intersection between planes  $P_1$  and  $P_2$ .

**interDD()**

The function **interDD(D1,D2,epsilon)** calculates and returns (if it exists) the intersection between lines  $D_1$  and  $D_2$ . The argument *epsilon* is  $10^{-10}$  by default (used to test whether a given float is zero).

**interCS()**

The function **interCS(C,S)** calculates and returns (if it exists) the intersection between the circle  $C = \{A, r, n\}$  ( $A$  is the center of the circle,  $r$  the radius, and  $n$  a normal vector to the plane of the circle), and the sphere  $S = \{B, R\}$  ( $B$  is the center of the sphere and  $R$  the radius). The function returns either *nil* (empty intersection), a single point, or two points (sequence).

**interDS()**

The function **interDS(d,S)** calculates and returns (if it exists) the intersection between the line  $d$  and the sphere  $S$  where  $S$  is a table  $S = \{C, r\}$  with  $C$  as the center (3d point) and  $r$  as the radius. The function returns either *nil* (empty intersection), a single point, or two points.

**interPS()**

The function **interPS(P,S)** calculates and returns (if it exists) the intersection between the plane  $P$  and the sphere  $S$  where  $S$  is a table  $S = \{C, r\}$  with  $C$  as the center (3d point) and  $r$  as the radius. The function returns either *nil* (empty intersection) or a sequence of the form  $I, r, n$ , where  $I$  is a 3D point representing the center of a circle,  $r$  its radius, and  $n$  a normal vector to the plane of the circle. This circle is the desired intersection.

**interSS()**

The function **interSS(S1,S2)** calculates and returns (if it exists) the intersection between the sphere  $S1 = \{C1, r1\}$  and  $S2 = \{C2, r2\}$ . The function returns either *nil* (empty intersection) or a sequence of the form  $I, r, n$ , where  $I$  is a 3D point representing the center of a circle,  $r$  its radius, and  $n$  a normal vector to the plane of the circle. This circle is the desired intersection.

**interSSS()**

The function **interSSS(S1,S2,S3)** calculates and returns (if it exists) the intersection between the spheres  $S1 = \{C1, r1\}$ ,  $S2 = \{C2, r2\}$  and  $S3 = \{C3, r3\}$ . The function returns either *nil* (empty intersection), a single point, or two points (sequence).

**merge3d()**

The function **merge3d(L)** combines, if possible, the connected components of  $L$ , which must be a list of lists of 3D points. The function returns the result.

**split\_points\_by\_visibility()**

The function **split\_points\_by\_visibility(L, visible\_function)**, where  $L$  is a list of 3D points, or a list of lists of 3D points, and where *visible\_function* is a function such that *visible\_function(A)* returns *true* if the 3D point  $A$  is visible, *false* otherwise, sorts the points of  $L$  according to whether they are visible or not. The function returns a sequence of two tables: *visible\_points*, *hidden\_points*.

```

1 \begin{luadraw}{name=curve_on_cylinder}

## IX More Advanced Examples

### 1) The Box of Sugars

The problem<sup>5</sup> is to draw sugars in a box. You need to be able to position the desired number of pieces, and wherever you want them in the box<sup>6</sup> without having to rewrite the entire code. Another constraint: to keep the figure as light as possible, only the facets actually seen should be displayed. In the code below, we keep the default viewing angles, and:

<sup>5</sup>Problem posed in a forum, the objective being to use it as counting exercises for students.

<sup>6</sup>A piece must rest either on the bottom of the box or on top of another piece

- the sugars are cubes of side 1 (we then modify the 3D matrix of the graph to "elongate" them),
- each piece is identified by the coordinates  $(x, y, z)$  of the upper right corner of the front face, with  $x$  an integer 1 and  $Lg$ ,  $y$  an integer between 1 and  $lg$ , and  $z$  an integer between 1 and  $ht$ .
- to store the positions of the pieces, we use a three-dimensional matrix *positions*, one for  $x$ , one for  $y$ , and one for  $z$ , with the convention that *positions*[ $x$ ][ $y$ ][ $z$ ] is 1 if there is a sugar at position  $(x, y, z)$ , and 0 otherwise.
- For each piece, there are at most three visible faces: the top one, the right one, and the front one.<sup>7</sup>, but we only draw the top face if there isn't another sugar cube above it, we only draw the right face if there isn't another sugar cube to the right, and we only draw the front face if there isn't another sugar cube in front. This builds the list of facets actually seen.
- In the scene display, you must **put the box first**, otherwise its facets will be cut off by the planes of the sugar cube facets. The sugar cube facets cannot be cut off by the box because they are all inside.

```

Figure 34: Box of Sugar Cubes

## 2) Stack of Cubes

We can modify the previous example to draw a stack of randomly positioned cubes, with four views. We'll position the cubes by placing a random number per column, starting from the bottom. We'll create four views of the stack, adding axes to help us navigate between these different views. This slightly changes the search for potentially visible facets; there are five cases per cube, not just three (front, back, left, right, and top; we don't create bottom views). To make the stack more readable, we use three colors to paint the cube faces (two opposite faces have the same color).

Figure 36: Illustration of Dandelin's Theorem

We want to draw a cone with a section through a plane and two spheres inside this cone (and tangent to the plane), but without drawing any spheres or faceted cones. The starting point, however, is the creation of these faceted solids, the spheres  $S1$  and  $S2$  (lines 11 and 8 of the listing) as well as the cone  $C$  in line 23. The drawing principle is as follows:

1. We separate the facets of the cone into two categories: the visible facets (facing the observer) and the others (variables  $V$  and  $H$  in line 30), which actually correspond to the front of the cone and the back of the cone.
2. We divide the two lists of facets with the plane (lines 31 and 32). Thus,  $V1$  corresponds to the front facets located above the plane and  $V2$  corresponds to the front facets located below the plane (same thing with  $H1$  and  $H2$  for the back).
3. We then draw the outline of  $H2$  with a gradient fill (only) (line 34).
4. We draw the small sphere (in orange, line 35).
5. We draw the outline of  $V2$  with a gradient fill and transparency to see the small sphere (line 36).
6. We draw the segment  $[S, P]$  (line 37) then the plane as a transparent facet (line 38).
7. We draw the outline of  $H1$  with a gradient fill (line 39). This is the back part above the plane.
8. We draw the large sphere (line 40).
9. Finally, we draw the outline of  $V1$  with a gradient fill (line 41) and transparency to see the sphere (this is the front part of the cone above the plane), then the opening of the cone (line 42).
10. We draw the intersections between the cone and the spheres (lines 44 and 45) as well as between the cone and the plane (line 46).

#### 4) Volume defined by a double integral

```

1 \begin{luadraw}{name=volume_integrale}
2 local i, pi, sin, cos = cpx.I, math.pi, math.sin, math.cos

```

```

3 local g = graph3d:new{window3d={-4,4,-4,4,0,6},adjust2d=true,margin={0,0,0,0},size={10,10}}

15 g:Dlabel3d("$x_1$", M(x1,4.75,0),{},{}, "$x_2$", M(x2,4.75,0),{},{}, "$y_1$", M(4.75,y1,0),{},{}, "$y_2$", M(4.75,y2,0),{},{},
16   "$0$",M(4,-4.75,0),{},{})
17 g:Show()
\end{luadraw}

```

Figure 37: Volume correspondant à  $\int_{x_1}^{x_2} \int_{y_1}^{y_2} f(x,y) dx dy$ 

Here, the solid represented has lateral faces (Fx1, Fx2, Fy1, and Fy2) with one side being a parametric curve. We therefore take the points of this parametric curve (its first connected component) and add the projections of the two ends onto the  $xOy$  plane. Care must be taken with the direction of travel so that the faces are correctly oriented (normal outward). This normal is calculated from the first three points of the face; it is best to start the face with the two projections onto the plane to be sure of the orientation. We draw the bottom first, then the lateral faces, and finish with the surface.

## 5) Volume defined on something other than a block

```

1 \begin{luadraw}{name=volume2}
2 local i = cpx.I
3 local g = graph3d:new{window3d={0,1,0,1,0,1}, margin={0,0,0,0},adjust2d=true,viewdir={170,40}, size={10,10}}
4 g:Labelsize("scriptsize")
5 local f = function(t) return M(t,t^2,0) end
6 local h = function(t) return M(1,t,t^2) end
7 local C = parametric3d(f,0,1,25,false,0)[1] -- courbe y=x^2 dans le plan z=0 (première composante connexe)
8 local D = parametric3d(h,1,0,25,false,0)[1] -- courbe y=y^2 dans le plan x=1, en sens inverse
9 local dessous = concat({M(1,0,0)},C) -- forme la face du dessous
10 local arriere = concat({M(1,1,0)},D) -- forme la face arrière
11 local avant, dessus, A, B = {}, {}, nil, C[1]
12 for k = 2, #C do --on construit les faces avant et de dessus facette par facette, en partant des points de C
13   A = B; B = C[k]

```

```

14     table.insert(avant, {B,A,M(A.x,A.y,A.y^2),M(B.x,B.y,B.y^2)})
15     table.insert(dessus, {M(B.x,B.y,B.y^2),M(A.x,A.y,A.y^2),M(1,A.y,A.y^2),M(1,B.y,B.y^2)})
16 end
17 g:Dboxaxes3d({grid=true, gridcolor="gray",fillcolor="LightGray", drawbox=false,
18     xyzstep=0.25, xlabelstyle="W",zlabelsep=0})
19 g:Lineoptions(nil,"Navy",8)
20 g:Dpolyline3d(arriere,close,"fill=Crimson",fill opacity=0.6) -- face arriere (plane)
21 g:Filloptions("fdiag","black"); g:Dpolyline3d(dessous,close) -- dessous
22 g:Dmixfacet(avant,{color="Crimson",opacity=0.7,mode=mShadedOnly}, dessus,{color="cyan",opacity=1})
23 g:Filloptions("none"); g:Dpolyline3d(concat(border(avant),border(dessous)))
24 g:Show()
25 \end{luadraw}

```

Figure 38: Volume :  $0 \leq x \leq 1$ ;  $0 \leq y \leq x^2$ ;  $0 \leq z \leq y^2$ 

In this example, the surface has the equation  $z = y^2$  (parabolic cylinder), but we are no longer on a block. The front face is not flat; we construct it like a cylinder (line 14) with vertical facets resting on curve  $C$  at the bottom, and on curve  $t \mapsto M(t, t^2, t^4)$  at the top.

Similarly, the top face (the surface) is constructed like a horizontal cylinder resting on curves  $D$  and  $t \mapsto M(t, t^2, t^4)$ .

We could not construct the surface by hand (called *top* in the code), and instead draw the following surface (after the front face):

```

1 g:Dfacet( surface(function(u,v) return M(u,v*u^2,v^2*u^4) end, 0,1,0,1), {mode=mShadedOnly, color="cyan"})

```

but it has many more facets ( $25 \times 25$ ) than the cylinder-shaped construction (21 facets), which is less interesting.

## X Extensions

### 1) The *luadraw\_polyhedrons* module

This module is still in draft form and is expected to be expanded in the future. As its name suggests, it contains the definition of polyhedra. All numerical data comes from the [Visual Polyhedra](#) website.

All functions follow the same model: **<name>(C,S,all)** where  $C$  is the center of the polyhedron (3D point) and  $S$  is a vertex of the polyhedron (3D point). When  $C$  or  $S$  have the value *nil*, the untransformed polyhedron (centered at the origin) is returned. The optional argument *all* is a boolean. When it has the value *true*, the function returns four things:  $P, V, E, F$  where:

- $P$  is the solid as a polyhedron,

- $V$  the list (table) of vertices,
- $E$  the list (table) of edges (with 3D points),
- $F$  the list of facets (with 3D points). Some polyhedra have multiple facet types; in this case, the returned result is of the form:  $P, V, E, F1, F2, \dots$ , where  $F1, F2, \dots$  are lists of facets. This can allow them to be drawn with different colors, for example.

The argument *all* is set to *false*, which is the default value; the function only returns the polyhedron.

Here are the solids currently contained in this module:

- The Platonic solids, these solids have only one face type:
  - The function **tetrahedron(C,S,all)** allows the construction of a regular tetrahedron with center  $C$  (3d point) and one vertex at  $S$  (3d point).
  - The function **octahedron(C,S,all)** allows the construction of an octahedron with center  $C$  (3d point) and one vertex at  $S$  (3d point).
  - The function **cube(C,S,all)** allows the construction of a cube with center  $C$  (3d point) and one vertex at  $S$  (3d point).
  - The function **icosahedron(C,S,all)** allows the construction of an icosahedron with center  $C$  (3d point) and one vertex at  $S$  (3d point).
  - The function **dodecahedron(C,S,all)** allows the construction of a dodecahedron with center  $C$  (3d point) and one vertex at  $S$  (3d point).
- The Archimedean Solids:
  - The function **cuboctahedron(C,S,all)** allows the construction of a cuboctahedron with center  $C$  (3d point) and one vertex at  $S$  (3d point). This solid has two types of faces.
  - The function **icosidodecahedron(C,S,all)** allows the construction of an icosidodecahedron with center  $C$  (3d point) and one vertex at  $S$  (3d point). This solid has two types of faces.
  - The function **lsnubcube(C,S,all)** allows the construction of a snub cube (form 1) with center  $C$  (3d point) and one vertex at  $S$  (3d point). This solid has two types of faces.
  - The function **lsnubdodecahedron(C,S,all)** allows the construction of a snub dodecahedron (form 1) with center  $C$  (3d point) and one vertex at  $S$  (3d point). This solid has two types of faces.
  - The function **rhombicosidodecahedron(C,S,all)** allows the construction of a rhombicosidodecahedron with center  $C$  (3d point) and one vertex at  $S$  (3d point). This solid has three types of faces.
  - The function **rhombicuboctahedron(C,S,all)** allows the construction of a rhombicuboctahedron with center  $C$  (3d point) and one vertex at  $S$  (3d point). This solid has two types of faces.
  - The function **rlnubcube(C,S,all)** allows the construction of a snub cube (shape 2) with center  $C$  (3d point) and one vertex at  $S$  (3d point). This solid has two types of faces.
  - The function **rlnubdodecahedron(C,S,all)** allows the construction of a snub dodecahedron (shape 2) with center  $C$  (3d point) and one vertex at  $S$  (3d point). This solid has two types of faces.
  - The function **truncatedcube(C,S,all)** allows the construction of a truncated cube with center  $C$  (3d point) and one vertex at  $S$  (3d point). This solid has two types of faces.
  - The function **truncatedcuboctahedron(C,S,all)** allows the construction of a truncated cuboctahedron with center  $C$  (3d point) and one vertex at  $S$  (3d point). This solid has three types of faces.
  - The function **truncateddodecahedron(C,S,all)** allows the construction of a truncated dodecahedron with center  $C$  (3d point) and one vertex at  $S$  (3d point). This solid has two types of faces.
  - The function **truncatedicosahedron(C,S,all)** allows the construction of a truncated icosahedron with center  $C$  (3d point) and one vertex at  $S$  (3d point). This solid has two types of faces.

- The function **truncatedicosidodecahedron(C,S,all)** allows the construction of a truncated icosidodecahedron with center  $C$  (3d point) and one vertex at  $S$  (3d point). This solid has two types of faces.
- The function **truncatedoctahedron(C,S,all)** allows the construction of a truncated octahedron with center  $C$  (3d point) and one vertex at  $S$  (3d point). This solid has two types of faces.
- The function **truncatedtetrahedron(C,S,all)** allows the construction of a truncated tetrahedron with center  $C$  (3d point) and one vertex at  $S$  (3d point). This solid has two types of faces.

- Other solids:

- The function **octahemioctahedron(C,S,all)** allows the construction of an octahemioctahedron with center  $C$  (3d point) and one vertex at  $S$  (3d point). This solid has two types of faces.
- The function **small\_stellated\_dodecahedron(C,S,all)** allows the construction of a small stellated dodecahedron with center  $C$  (3d point) and one vertex at  $S$  (3d point). This solid has only one type of face.

Figure 39: Polyhedra from the *luadraw\_polyhedrons* module

## 2) The *luadraw\_spherical*

### Module

This module allows you to draw a number of objects on a sphere (such as circles, spherical triangles, etc.) without having to manually manage the visible or invisible parts. Drawing is done in three steps:

1. We define the characteristics of the sphere (center, radius, color, etc.)
2. We define the objects to be added to the scene using dedicated methods.
3. We display everything with the **g:Dspherical()** method.

Of course, all 2D and 3D drawing methods remain usable.

### Global Module Variables and Functions

- Variables with their default values:
  - **Insidelabelcolor** = "DarkGray": Defines the color of labels whose anchor point is inside the sphere.
  - **arrowBstyle** = ">": Type of arrow at the end of the line
  - **arrowAstyle** = "<": Type of arrow at the beginning of the line
  - **arrowABstyle** = "<->": Very rarely used because most of the time the lines drawn on the sphere must be cut.
- Functions:
  - **sM(x,y,z)**: returns a point on the sphere; this is the point  $I$  on the sphere such that the half-line  $[O, I)$  ( $O$  being the center of the sphere) passes through the point  $A$  with Cartesian coordinates  $(x, y, z)$ . It is the projection of the point  $(Mx, y, z)$  onto the sphere from the center.
  - **sM(theta,phi)**: where  $\theta$  and  $\phi$  are angles in degrees, returns a point on the sphere, whose spherical coordinates are  $(R, \theta, \phi)$  where  $R$  is the radius of the sphere.
  - **toSphere(A)**: returns the projection of point  $A$  onto the sphere from the center.
  - **clear\_spherical()**: removes objects that have been added to the scene, and resets the values to their default values.

If the global variable **Hiddenlines** is set to *true*, then the hidden parts will be drawn in the style defined by the global variable **Hiddenlinestyle**. However, this behavior can be modified using the local option *hidden=true/false*.

### Sphere Definition

By default, the sphere is centered at the origin, has a radius of 3, and is orange, but this can be modified with the **g:Define\_sphere( options )** method, where *options* is a table allowing you to adjust each parameter. These are as follows (with their default values in parentheses):

- `center` = (Origin),
- `radius` = (3),
- `color` = ("Orange"),
- `opacity` = (1),
- `mode` = (*mBorder*), sphere display mode (*mWireframe* or *mGrid* or *mBorder*, see **Dsphere**),
- `edgecolor` = ("LightGray"),
- `edgestyle` = ("solid"),
- `hiddenstyle` = (Hiddenlinestyle),
- `hiddencolor` = ("gray"),
- `edgewidth` = (4),
- `show` = (true), to show or hide the sphere.

### Add a circle: g:DScircle

The **g:DScircle(P,options)** method allows you to add a circle to the sphere. The argument *P* is a table of the form  $\{A, n\}$  that represents a plane (passing through *A* and normal to *n*, two 3D points). The circle is then defined as the intersection of this plane with the sphere. The *options* argument is a table with 5 fields, which are:

- `style` = (current line style),
- `color` = (current line color),
- `width` = (current line thickness in tenths of a point),
- `opacity` = (current line opacity),
- `hidden` = (value of *Hiddenlines*),
- `out` = (nil), if we assign a list variable to this *out* parameter, then the function adds to this list the two points corresponding to the ends of the hidden arc, if any, which allows us to retrieve them without having to calculate them.

### Add a great circle: g:DSbigcircle

The method **g:DSbigcircle(AB,options)** adds a great circle to the sphere. The argument *AB* is a table of the form  $\{A, B\}$  where *A* and *B* are two distinct points on the sphere. The great circle is then the circle centered at the center of the sphere, and passing through *A* and *B*. The *options* argument is a table with 5 fields, which are:

- `style` = (current line style),
- `color` = (current line color),
- `width` = (current line thickness in tenths of a point),
- `opacity` = (current line opacity),

- `hidden` = (value of *Hiddenlines*),
- `out` = (nil), if we assign a table-type variable to this *out* parameter, then the function adds to this list the two points corresponding to the endpoints of the hidden arc, if any, which allows us to retrieve them without having to calculate them.

### Add a great circle arc: `g:DSarc`

The method `g:DSarc(AB,sens,options)` allows you to add a great circle arc to the sphere. The argument *AB* is a table of the form  $\{A,B\}$  where *A* and *B* are two distinct points on the sphere. The great circle arc is then drawn from *A* to *B*. The argument *sens* is equal to 1 or -1 to indicate the direction of the arc. When *A* and *B* are not diametrically opposed, the plane *OAB* (where *O* is the center of the sphere) is oriented with  $\vec{OA} \wedge \vec{OB}$ . The *options* argument is a table with 6 fields, which are:

- `style` = (current line style),
- `color` = (current line color),
- `width` = (current line thickness in tenths of a point),
- `opacity` = (current line opacity),
- `hidden` = (value of *Hiddenlines*),
- `arrows` = (0), three possible values: 0 (no arrow), 1 (one arrow at *B*), 2 (arrow at *A* and *B*).
- `normal` = (nil), allows you to specify a normal vector to the *OAB* plane when these three points are aligned.

### Add an angle: `g:DSangle`

The method `g:DSangle(B,A,C,r,sens,options)`, where *A*, *B*, and *C* are three points on the sphere, allows you to draw a great circle arc on the sphere to represent the angle  $(\vec{AB}, \vec{AC})$  with a radius of *r*. The argument *sens* is 1 or -1 to indicate the direction of the arc; the plane *ABC* is oriented with  $\vec{AB} \wedge \vec{AC}$ . The *options* argument is a table with 6 fields, which are:

- `style` = (current line style),
- `color` = (current line color),
- `width` = (current line thickness in tenths of a point),
- `opacity` = (current line opacity),
- `hidden` = (value of *Hiddenlines*),
- `arrows` = (0), three possible values: 0 (no arrow), 1 (one arrow at *B*), 2 (arrow at *A* and *B*).
- `normal` = (nil), allows you to specify a normal vector to the *ABC* plane when these three points are "aligned" on the same great circle.

### Add a spherical facet: `g:DSfacet`

The method `g:DSfacet(F,options)`, where *F* is a list of points on the sphere, allows you to draw the facet represented by *F*, the edges being great circle arcs. The *options* argument is a table with 6 fields, which are:

- `style` = (current line style),
- `color` = (current line color),
- `width` = (current line thickness in tenths of a point),
- `opacity` = (current line opacity),
- `hidden` = (value of *Hiddenlines*),
- `fill` = (""), string representing the fill color (none by default),
- `fillopacity` = (0.3), opacity of the fill color.

**Add a spherical curve: g:DScurve**

The method **g:DScurve(L,options)**, where  $L$  is a list of points on the sphere, allows you to draw the curve represented by  $L$ . The *options* argument is a table with six fields, which are:

- **style** = (current line style),
- **color** = (current line color),
- **width** = (current line thickness in tenths of a point),
- **opacity** = (current line opacity),
- **hidden** = (value of *Hiddenlines*),
- **out** = (nil). If we assign a table-type variable to this *out* parameter, then the function adds the points corresponding to the ends of the hidden parts to this list.

We will now deal with objects that are not necessarily on the sphere, but that may pass through it, or be inside it, or outside it.

**Add a segment: g:DSseg**

The **g:DSseg(AB,options)** method allows you to add a segment. The argument  $AB$  is a table of the form  $\{A,B\}$  where  $A$  and  $B$  are two points in space. The function handles interactions with the sphere. The *options* argument is a table with 5 fields, which are:

- **style** = (current line style),
- **color** = (current line color),
- **width** = (current line thickness in tenths of a point),
- **opacity** = (current line opacity),
- **hidden** = (value of *Hiddenlines*),
- **arrows** = (0), three possible values: 0 (no arrow), 1 (one arrow in  $B$ ), 2 (arrow in  $A$  and  $B$ ).

**Add a line: g:DSline**

The **g:DSline(d,options)** method allows you to add a line. The argument  $d$  is a table of the form  $\{A,u\}$  where  $A$  is a point on the line and  $u$  is a direction vector (two 3D points). The function handles interactions with the sphere. The drawn segment is obtained by intersecting the line with the 3D window; it may be empty if the window is too narrow. The *options* argument is a table with 6 fields, which are:

- **style** = (current line style),
- **color** = (current line color),
- **width** = (current line thickness in tenths of a point),
- **opacity** = (current line opacity),
- **hidden** = (value of *Hiddenlines*),
- **arrows** = (0), three possible values: 0 (no arrow), 1 (one arrow at  $B$ ), 2 (arrow at  $A$  and  $B$ ),
- **scale** = (1), allows you to change the size of the plotted segment.

**Add a polygonal line: g:DSpolyline**

The **g:DSpolyline(L,options)** method allows you to add a polygonal line. The argument *L* is a list of points in space, or a list of lists of points in space. The function handles interactions with the sphere. The *options* argument is a table with 6 fields, which are:

- **style** = (current line style),
- **color** = (current line color),
- **width** = (current line thickness in tenths of a point),
- **opacity** = (current line opacity),
- **hidden** = (value of *Hiddenlines*),
- **arrows** = (0), three possible values: 0 (no arrow), 1 (one arrow at *B*), 2 (arrow at *A* and *B*),
- **close** = (false), indicates whether the line should be closed.

**Add a plane: g:DSplane**

The **g:DSplane(P,options)** method allows you to add the contour of a plane. The argument *P* is a table of the form  $\{A,n\}$ , where *A* is a point on the plane and *n* is a normal vector. The function draws a parallelogram representing the plane *P*, processing the interactions with the sphere. The *options* argument is a table with 7 fields, which are:

- **style** = (current line style),
- **color** = (current line color),
- **width** = (current line thickness in tenths of a point),
- **opacity** = (current line opacity),
- **hidden** = (value of *Hiddenlines*),
- **scale** = (1), allows you to change the size of the parallelogram,
- **angle** = (0), angle in degrees, allows you to rotate the parallelogram around the perpendicular line passing through the center of the sphere.
- **trace** = (true), allows you to draw, or not, the intersection of the plane with the sphere when it is not empty.

**Add a label: g:DStlabel**

The **g:DStlabel(text1,anchor1,options1,text2,anchor2,options2,...)** method allows you to add one or more labels using the same principle as the *g:Dlabel3d* method, except that here the function handles cases where the anchor point is inside the sphere, behind the sphere, or in front of the sphere. When it is inside, the label color is given by the global variable **Insidelabelcolor**, which defaults to "DarkGray".

**Add points: g:DSdots and g:DSstars**

The **g:DSdots(dots,options)** method allows you to add points to the scene. The *dots* argument is a list of 3D points. The function draws points by managing interactions with the sphere. The *options* argument is a two-field table, which are:

- **hidden** = (value of *Hiddenlines*),
- **mark\_options** = (""), a string that will be passed directly to the *\draw* instruction.

If a point is inside the sphere, or on the hidden face, the point's color is given by the global variable **Insidelabelcolor**, which defaults to "DarkGray".

The **g:DSstars(dots,options)** method allows you to add points to the sphere. The *dots* argument is a list of 3D points that will be projected onto the sphere. The function draws these points as an asterisk. The *options* argument is a two-field table, which are:

- `style` = (current line style),
- `color` = (current line color),
- `width` = (current line thickness in tenths of a point),
- `opacity` = (current line opacity),
- `hidden` = (value of *Hiddenlines*),
- `scale` = (1), allows you to change the size of the parallelogram,
- `circled` = (false), allows you to add a circle around the star,
- `fill` = (""), string representing a color. When not empty, the asterisk is replaced by a circled hexagonal facet and filled with the color specified by this option.

The points on the hidden face of the sphere have the color given by the global variable **Insidelabelcolor**, which defaults to "DarkGray".

### Inverse Stereography: `g:DSinvstereo_curve` and `g:DSinvstereo_polyline`

The method `g:DSinvstereo_curve(L,options)`, where  $L$  is a 3D polygonal line representing a curve drawn on a plane with equation  $z = cte$ , draws the image of  $L$  on the sphere by inverse stereography, the pole being the point  $C+r*vecK$ , where  $C$  is the center of the sphere and  $r$  is the radius.

The method `g:DSinvstereo_polyline(L,options)`, where  $L$  is a 3D polygonal line drawn on a plane with equation  $z = cte$ , draws the image of  $L$  on the sphere by inverse stereography, the pole being the point  $C+r*vecK$ , where  $C$  is the center of the sphere and  $r$  is the radius.

In both cases, the *options* are the same as for the `g:DScurve` method.

### Examples

```

1 \begin{luadraw}{name=cube_in_sphere}
2 local g = graph3d:new{window={-9,9,-4,5},viewdir={25,70},size={16,8}}
3 require 'luadraw_spherical'
4 arrowBstyle = "-stealth"
5 g:Linewidth(6); Hiddenlinestyle = "dashed"
6 local a = 4
7 local O = Origin
8 local cube = parallelepiped(0,a*vecI,a*vecJ,a*vecK)
9 local G = isobar3d(cube.vertices)
10 cube = shift3d(cube,-G) -- to center the cube at the origin
11 local R = pt3d.abs(cube.vertices[1])
12
13 local dessin = function()
14     g:DSPolyline({{0,5*vecI},{0,5*vecJ},{0,5*vecK}}, {arrows=1, width=8}) -- axes
15     g:DSPlane({a/2*vecK,vecK},{color="blue",scale=0.9,angle=20});
16     g:DSCircle({-a/2*vecK,vecK},{color="blue"})
17     g:DSPolyline(facetedges(cube)); g:DLabel("$O$",0,{pos="W"})
18     g:Dspherical()
19 end
20
21 g:Saveattr(); g:Viewport(-9,0,-4,5); g:Coordsystem(-5,5,-5,5)
22 Hiddenlines = true; g:Define_sphere({radius=R})
23 dessin()
24 g:DLabel3d("$x$",5*vecI,{pos="SW"}, "$y$",5*vecJ,{pos="E"}, "$z$",5*vecK,{pos="N"})
25 g:DLabel("Hiddenlines=true",0.5-4.5*cpx.I,{})
26 g:Restoreattr()
27
28 clear_spherical() -- deletes previously created objects
29
30 g:Saveattr(); g:Viewport(0,9,-4,5); g:Coordsystem(-5,5,-5,5)
31 Hiddenlines = false; g:Define_sphere({radius=R,opacity=0.7})

```

```

32 dessin()
33 g:Dlabel3d("$x$",5*vecI,{pos="SW"},"$y$",5*vecJ,{pos="E"},"$z$",5*vecK,{pos="N"})
34 g:Dlabel("Hiddenlines=false, opacity=0.7",0.5-4.5*cpx.I,{})
35 g:Restoreattr()
36 g:Show()
37 \end{luadraw}

```

Figure 40: Cube in a Sphere

### Spherical curve

```

1 \begin{luadraw}{name=courbe_spherique}
2 local g = graph3d:new{window={-4.5,4.5,-4.5,4.5},viewdir={30,60},margin={0,0,0,0},size={10,10}}
3 require 'luadraw_spherical'
4 arrowBstyle = "-stealth"
5 g:Linewidth(6); Hiddenlinestyle = "dotted"
6 Hiddenlines = false;
7 local C = cylinder(M(1.5,0,-3.5),1.5,M(1.5,0,3.5),35,true)
8 local L = parametric3d( function(t) return Ms(3,t-math.pi/2,t) end, -math.pi,math.pi) -- la courbe
9 g:Define_sphere()
10 g:DSpolyline(facetedges(C),{color="gray"}) -- affichage cylindre
11 g:DSpolyline({{-5*vecI,5*vecI},{-5*vecJ,5*vecJ},{-5*vecK,5*vecK}},{arrows=1}) -- axes
12 Hiddenlines=true; g:DScurve(L,{width=12,color="blue"}) -- courbe avec partie cachée
13 g:Dspherical()
14 g:Show()
15 \end{luadraw}

```

Figure 41: Viviani window

To avoid compromising the readability of the drawing, the hidden parts have not been displayed except for the curve.

### A spherical tiling

```

1 \begin{luadraw}{name=pavage_spherique}
2 local g = graph3d:new{window={-3,3,-3,3},viewdir={30,60},size={10,10}}
3 require 'luadraw_spherical'
4 require "luadraw_polyhedrons"
5 g:Linewidth(6); Hiddenlines = true; Hiddenlinestyle = "dotted"
6 local P = poly2facet( octahedron(Origin,SM(30,10)) )
7 local colors = {"Crimson","ForestGreen","Gold","SteelBlue","SlateGray","Brown","Orange","Navy"}
8 g:Define_sphere()
9 for k,F in ipairs(P) do
10     g:DSfacet(F,{fill=colors[k],style="noline",fillopacity=0.7}) -- facettes sans les bords
11 end
12 for _, A in ipairs(facetedges(P)) do
13     g:DSarc(A,1,{width=8}) -- each edge is an arc of a great circle
14 end
15 g:Dspherical()
16 g:Show()
17 \end{luadraw}

```

Figure 42: A spherical tiling

For this spherical tiling, we chose a regular octahedron with a center identical to that of the sphere and with one vertex on the sphere (and therefore all vertices are on the sphere).

### Tangents to the sphere from a point

```

1 \begin{luadraw}{name=tangent_to_sphere}
2 local g = graph3d:new{window={-4,5.5,-4,4},viewdir={30,60},size={10,10}}
3 require 'luadraw_spherical'
4 Hiddenlines=true; g:Linewidth(6)
5 local O, I = Origin, M(0,6,0)
6 local S,S1 = {0, 3}, {(I+O)/2,pt3d.abs(I-O)/2}
7 -- the circle of tangency is the intersection between spheres S and S1
8 local C,r,n = interSS(S,S1)
9 local L = circle3d(C,r,n)[1] -- list of 3d points on the circle
10 local dots, lines = {}, {}
11 -- draw
12 g:Define_sphere({opacity=1})
13 g:DScircle({C,n},{color="red"})
14 for k = 1, math.floor(#L/4) do
15     local A = L[4*(k-1)+1]
16     table.insert(dots,A)
17     table.insert(lines,{I, 2*A-I})
18 end
19 g:DSpolyline(lines,{color="gray"})
20 g:DStars(dots) -- drawing points on the sphere
21 g:DSDots({O,I}); -- points in the scene
22 g:DLabel("$I$",I,{pos="S",node_options="red"},"$O$",O,{})
23 g:Dspherical()
24 g:Dseg3d({O,dots[1]},"gray,dashed"); g:Dangle3d(O,dots[1],I,0.2,"gray")
25 g:Show()
26 \end{luadraw}

```

Figure 43: Tangents to the sphere from a point

### Inverse Stereography

```

1 \begin{luadraw}{name=stereographic_curve}
2 local g = graph3d:new{window3d={-5,5,-2,2},window={-4.25,4.25,-2.5,2},size={10,10}, viewdir={40,70}}
3 Hiddenlines = true; Hiddenlinestyle="dashed"; g:Linewidth(6)
4 require 'luadraw_spherical'
5 local C, R = Origin, 1
6 local a = -R

### 3) The *luadraw\_palettes* Module

The *luadraw\_palettes* Module<sup>8</sup> defines 128 color palettes, each with a name. A palette is a list (table) of colors, which are themselves lists of three numerical values between 0 and 1 (red, green, and blue components). The list of these palettes, as well as their rendering, can be viewed in this [document](#). More informations in this [document](#) of Christophe BAL.

### 4) The *luadraw\_compile\_tex* module

**Warning:** This module requires that the programs *pdf2ps* and *pstoedit* be installed on your system.

This module allows you to:

1. compile a text fragment in TeX,
2. convert the resulting file into an *eps* file containing "flattened PostScript",
3. read the content of the *eps* file and return its content as a list of paths, with the line thickness at the beginning of each path, and the fill instruction at the end.
4. The list thus obtained can be:
  - (a) drawn on the screen,
  - (b) converted into 3D paths in a given plane and drawn,
  - (c) converted into 3D polygonal lines in a given plane (the thickness and fill command are then lost) and drawn.

#### Part One: Compilation and Reading

**Warning :** This step requires compiling the document with the *-shell-escape* or *-enable-write18* option. Without this option, the fragment will not be compiled, which is not a problem if the *<filename>.eps* file already exists and you did not intend to modify it.

The first step is handled by the **compile\_tex(text,filename)** function. The *text* argument is a string; this is the fragment to be compiled. The optional *filename* argument is also a string; this is the name of the file that will be created. This name must not contain **a path or an extension**. By default, this name is *"tex2FlatPs"*. It is created in the current directory (but will then be deleted). The process unfolds in several steps:

1. Creation of the TeX file. This uses two global variables:
 

```
preamble = "\\documentclass[12pt]{article}\n"
usepackage = "\\usepackage{amsmath,amssymb}\n\\usepackage{fouriernc}\n"
```

 Compilation is performed with LuaLaTeX.
2. The resulting file is converted to PostScript using the *pdf2ps* utility.
3. The resulting PS file is then converted using the *pstoedit* utility into an EPS file in flattened PostScript (all content is in the form of paths).
4. The resulting file *<filename>.eps* is copied to the working directory of *luadraw* (the name of this directory is in the global variable *cachedir*), and all compilation remnants are erased.
5. The contents of the file thus created are automatically read by the function *read\_compiled\_tex(filename)*, which returns a list of paths. Each path is a list starting with the line thickness, followed by dots and instructions like a regular path, and ending with the fill command ("*fill*", "*eofill*", or "*stroke*").

---

<sup>8</sup>This module is a contribution of [Christophe BAL](#).

## Part Two: Using the Result

**In 2D** The result can be drawn using the method **g:Dcompiled\_tex(anchor, L, options)** where  $L$  is the result returned by the function `compile_tex()`. The *anchor* argument is a complex number; it represents the center of the bounding box of the drawing contained in  $L$ . The *options* argument is a table whose fields are:

- `scale = (1)`, allows you to adjust the size of the drawing, this option can be a number or a table of two numbers:  $\{scaleX, scaleY\}$ ,
- `color = (current default color)`,
- `dir = (nil)`, a table consisting of two vectors  $\{v1, v2\}$  indicating the writing direction (nil means the usual direction, which corresponds to the table  $\{1, cpx.I\}$ ),
- `hollow = (false)`, enables or disables the filling of shapes. With the value *true*, only the outlines are drawn.
- `drawbox = (false)`: allows you to draw or not draw the bounding box,
- `draw_options = (")`: string containing the options that will be passed directly to the `\draw` command.

The result can also be transformed into a polygonal line using the function **compiled\_tex2polyline(L, scale)** where  $L$  is the result returned by the `compile_tex()` function. The optional argument *scale* allows you to adjust the size; it can be a number or a table of two numbers:  $\{scaleX, scaleY\}$ .

```

1 \begin{luadraw}{name=compile_tex2d}
2 local g = graph:new{bbox=false}
3 require 'luadraw_compile_tex'
4 local i = cpx.I
5 local text = "\\int_0^{+\\infty} e^{-\\frac{x^2}{2}}dx = \\frac{\\sqrt{2\\pi}}{2}" -- text to compile
6 local L = compile_tex(text, "gauss_integral") -- compile with -shell-escape the first time to create the file
7 g:Shift(2*i) -- a first drawing
8 g:Dcompiled_tex(0,L,{scale=2,hollow=true, drawbox=true, draw_options="fill=pink", dir={1-i/4,i}}) -- we draw L
9
10 g:Shift(-4*i) -- a second drawing
11 L = compiled_tex2polyline(L,{3,3}) -- L is converted to a polygonal line
12 local f = function(z) return Z(z.re,z.im+math.sin(z.re*1.5)) end -- this function produces sinusoidal waves
13 L = ftransform(L,f) -- we apply f to L
14 g:Dpath( polyline2path(L), 'draw=none,fill=blue') -- we draw L as a path
15 g:Show()
16 \\end{luadraw}

```

Figure 45: Example with `compile_tex` in 2d

$$\int_0^{+\infty} e^{-\frac{x^2}{2}} dx = \frac{\sqrt{2\pi}}{2}$$

**In 3D** The result can be converted to 3D using the method `g:Compiled_tex2path3d(L,options)` where  $L$  is the result returned by the function `compile_tex()`. The *options* argument is a table whose fields are:

- `scale` = (1), allows you to adjust the size of the drawing, this option can be a number or a table of two numbers:  $\{scaleX, scaleY\}$ ,
- `anchor` = (Origin), 3D point which represents the center of the bounding box of the drawing,
- `color` = (current default color),
- `dir` = ({vecJ,vecK}), basis of the plane in which the result will be located (this plane will also contain the *anchor* point), these two vectors indicate the direction of writing,
- `polyline` = (false), with the value *true* the returned result will be a list of lists of 3D points and can therefore be drawn with the method `g:Dpolyline3d()`, however, the information: line thickness and fill command, are lost. With the value *false* the result is a list of paths, each path is a list starting with the line thickness, followed by 3D points and instructions like an ordinary 3D path, and ending with the fill command ("*fill*", or "*eofill*" or "*stroke*").

With the option `polyline=false` (default value), the output can be drawn using the method `g:Dcompiled_tex3d(L,options)` where  $L$  is the result of the method `g:Compiled_tex2path3d()`. The argument *options* is an array whose fields are:

- `color` = (default current color),
- `hollow` = (false), enables or disables shape fills. With the value *true*, only outlines are drawn,
- `drawbox` = (false): allows you to draw or not draw the bounding box,
- `draw_options` = (""): string containing the options that will be passed directly to the `\draw` command.

```

31 g:Dpath3d(Cv, "draw=none,fill=red")
32 g:Show()
33 \end{luadraw}

```

Figure 46: Write on a cylinder

## XI History

### 1) Version 2.4

Non-exhaustive list:

- Added the central projection.
- Added the *legendstyle* option for axes, to impose a label style ("auto", "N", "E", ...) for legends when there are any (until now, the style was necessarily "auto").
- Added the *g:Labeldir()* method which allows global management of the writing direction.
- Added the functions *interCS()* (intersection between a circle in space and a sphere), and the function *interSSS()* (intersection between 3 spheres).
- Added the function *voronoi()* as a complement to Delaunay triangulation, it allows you to make Voronoi diagrams.
- Added the function *parallel\_polyline()* which returns a parallel polygonal line.
- Added the function *tangent\_from()* and the method *g:Dtangent\_from()* which allows drawing the tangents to a given curve from a given point.
- Bug fix...

### 2) Version 2.3

Non-exhaustive list:

- Added cavalier perspective projections: on *yz*, on *xz* or on *xy*, as well as the isometric projection.
- Added the function *section2tube()*.
- Added the *luadraw\_compile\_tex* module.
- Added the *Proj3dV* method for calculating the projection of space vectors onto the screen plane.
- Added the functions *circumcircle()* and *incircle()* in 2d, they return a sequence: center and radius.

- Added the function *line2strip()* which returns a path representing a "strip" centered on a given polygonal line.
- Added the function *delaunay()* which performs a Delaunay triangulation on a list of points and returns the list of triangles obtained.
- Added the function *cpx.normalize(z)* which returns the complex number *z* divided by its modulus (or *nil* if it is zero).
- Added the instruction *whatis(variable, msg)* which displays the status of a *variable* (along with the message *msg*) and its contents in the terminal.
- Bug fix...

### 3) Version 2.2

Non-exhaustive list:

- Added the *clip* option for the methods: *Dfacet()*, *Dmixfacet()*, *addFacet()*, *addPoly()* and *addPolyline()*, as well as for point cloud drawing methods, and line drawing methods such as *Dpolyline3d()*, *Dparametric3d()*, *Dpath3d()*, etc.
- Added the *xyzstep* option for the *Dboxaxes3d()* method. This option defines a common step for all three axes (1 by default).
- Added the *DSdots()*, *DSstars()*, *DSinvstereo\_curve()*, and *DSinvstereo\_polyline()* methods to the *luadraw\_spherical* module.
- Added the *luadraw\_palettes* module.
- Added the *interDC()* function (intersection between a line and a circle in 2D) and the *interCC()* function (intersection between two circles in 2D).
- Added the *curvilinear\_param()* and *curvilinear\_param3d()* functions, which allow you to parameterize a list of points (one in 2D and the other in 3D) with a function of a variable *t* between 0 and 1. Added the function *cvx\_hull2d()*, which returns the convex hull (polygonal line) of a list of points in 2D, and the function *cvx\_hull3d()*, which returns the convex hull (list of facets) of a list of points in 3D. Added the methods *g:Beginclip(<path>)* and *g:Endclip()*, which make it easier to set up clipping using tikz. Added the functions *normal()*, *normalC()*, and *normalI()*, which return the normal to a 2D curve at a given point. The corresponding graphics methods have also been added. Added the function *isobar()*, which returns the isobarycenter of a list of complexes. Added the *usepalette={palette,mode}* option for the *Dpoly*, *Dfacet*, *Dmixfacet*, and *addFacet* methods. Added the *clipplane()* function, which allows you to clip a plane with a convex polyhedron. The function returns the section, if it exists, as a facet. Added the *cartesian3d()* and *cylindrical\_surface()* functions, which calculate and return surfaces, with the option to add dividing walls for the *Dscene3d()* method.
- Added the function *evalf(f,...)* which allows a protected evaluation of *f(...)*. It returns the result of the evaluation if there is no runtime error from Lua, otherwise it returns *nil* but without causing the script execution to terminate.
- Added the function *split\_points\_by\_visibility()* (3d) to separate a curve into two parts: visible part, hidden part.
- In the methods *g:Dfacet*, *g:Dmixfacet*, *g:Dpoly*, *g:Dedges*, *g:addFacet*, *g:addPolyline*, *g:addPoly*, the default values for the line drawing options (thickness, color, and style) are the current values. Bug fix... ..
- Graduated axes (2d, 3d) use the *siunitx* package to format labels when the global variable *siunitx* is set to *true*.
- Added upright and slanted truncated cones (**frustum** and **Dfrustum**).
- Added regular pyramids (**regular\_pyramid** and truncated pyramids **truncated\_pyramid**).
- Cylinders and cones are no longer necessarily upright; they can now be slanted.
- Added the **cutpolyline(L,D,close)** function.
- (Elementary) drawing of sets (*set* function) and operations on sets (*cap*, *cup*, *setminus*).

- Modification of the *mode* argument of the **g:Dplane** method.
- Addition of the *close* option for the **g:addPolyline** method.
- Bug fix...

#### 4) Version 2.0

- Introduction of the *luadraw\_graph3d.lua* module for 3D drawings.
- Introduction of the *dir* option for the **g:Dlabel** method.
- Minor changes in color management.

#### 5) Version 1.0

First version.
